MEMORANDUM

TO: Lynne Welsh, Susanne Kayser, Jeremy Laird

FROM: Pam Moss-EA Project Manager, Sandy Staigerwald-EA Program Manager

DATE: 22 April 2016

SUBJECT: Accelerated Operable Unit 1 (AOU-1), East Side Springs 700 South 1600 East PCE Plume Salt Lake City, Utah – Temporary Groundwater Well Installation Inspection Memorandum

Introduction

This memorandum has been prepared for the Department of Veterans Affairs (VA) by EA Engineering, Science and Technology, Inc., PBC (EA) to document the final site conditions of borings/temporary groundwater wells installed in public right-of-ways in support of the Geoprobe® shallow groundwater investigation at AOU-1. The site conditions for the borings/temporary groundwater wells have been inspected by Salt Lake City Public Way Construction Inspector, Kevin Liptrot, and have been deemed acceptable by the inspector.

To assess the nature and extent of the 700 South 1600 East PCE Plume and to characterize vapor intrusion potential, temporary small-diameter groundwater monitoring points were installed throughout the East Side Springs area of AOU-1. A total of 50 boring locations were drilled in public right-of-ways and private property using a GeoProbe® drill rig with manual driven 2.25-inch rods during the period of 22 February to 8 March 2016. Of these 50 borings, 44 locations were converted to temporary groundwater monitoring points. After an initial round of groundwater sampling, 10 of the 44 points were completed as temporary monitoring wells to accomodate two additional groundwater sampling events. The remaining 34 monitoring points were abandonend and the sites were restored to their original condition (8 March to 6 April 2016).

All boring locations were drilled in soft surfaces (i.e. grass, dirt, and gravel), therefore no asphalt or concrete work was required to restore the locations. The top foot of the abandoned boreholes was filled with topsoil to match the surrounding area.

Site Inspection

Six of the 50 borings were located on private property. The remaining 44 borings were located in public right-of-ways and required a Permit to Work in the Public Way from the Division of Engineering prior to drilling. Per the Permit to Work on the Public Way, an assigned inspector would be contacted prior to commencing work and would be updated regularly on the status of the project. The permit also specifies that the permitee will restore all public way facilities modified by the permittee to a condition that is comparable to or better than the condition that existed prior to the commencement of the work.

The Construction Inspector was contacted daily regarding the quantity and locations of borings completed. Mr. Liptrot inspected the locations daily and deemed the final site conditions at all of the boring locations to be acceptable and comply with Salt Lake City standards. The Salt Lake City Division of Engineering does not have an official form that they provide to permitees stating that the work has

been inspected, however an email was received from Mr. Liptrot on 15 April 2016 stating that he approved the final restored condition of the Geoprobe® boring locations (Attachment 1).

Attachment

1 Email Correspondance from Salt Lake City – Final Site Inspection Approval

Lazzeri, Kristin

From: Liptrot, Kevin <Kevin.Liptrot@slcgov.com>
Sent: Friday, April 15, 2016 7:32 AM
To: Lazzeri, Kristin
Cc: Weiler, Scott
Subject: sample wells VA Project.

All the drill sites have been complete 34 ea. This sites are all acceptable for SLC standards and restoration is complete.

Ecological Assessment Checklists

THIS PAGE INTENTIONALLY LEFT BLANK

CHECKLIST FOR ECOLOGICAL ASSESSMENT / SURFACE WATER SAMPLING

Site Name: 700 S 1600 East PCE Plume

Date: ~~5/3/16~~ KL 5/4/16 Time: 1400 Temperature: 82°F Precipitation (24 hr): 0

Surface Water Sample Location: SW-01

Sample location site use description (circle one): (residential parcel) commercial parcel, industrial, park, other: _____

Seep? (Y) / N

Spring? Y / (N)

Pond? Y / (N)

Creek/Stream? Y / (N)

Describe and estimate flow (i.e., (barely accumulating seep) spring with noticeably free flowing water, ponded area [depth], creek [width, depth]. : water accumulating at about 0.1L/min

Describe area immediately surrounding the surface water location. Circle all that apply: mowed lawn, (sidewalk), street, (ornamental planting/garden), wild grass, brush, maintained trees, unmaintained/undisturbed woods, ravine, other. Description: seep is coming out of sidewalk/front yard

Describe surrounding habitat (within 200 feet of sampling location), circle all that apply: (mowed lawn), (ornamental planting/garden), wild grass, brush, (sporadic/maintained tree plantings), unmaintained woods, other. Description: residential neighborhood

Do any potentially sensitive environmental areas exist adjacent to or in proximity to the site? For example, flood plains, wetlands? Y / (N) Describe: _____

Are there any wooded areas on the parcel? Y / (N) What percentage of the parcel is wooded? ____

What is dominant type of vegetation in wooded area (circle one): evergreen / deciduous.
What is predominant size of trees on the parcel (diameter at breast height) (circle one): 0-6 in., 6-12 in., > 12 in.

Is shrub/scrub vegetation present at the parcel? Y / N. What percentage of the parcel is shrub/scrub vegetation? —. Is the shrub/scrub unmaintained (wild) or maintained (circle one). Average height of the shrub/scrub: 0-2ft, 2-2.5 ft, > 5 ft. Is scrub/shrub dense, patchy or sparse (circle one).

Are there open field areas present on the parcel? Y / N. What percentage of the parcel is open field / lawn? 40%. What is the predominant height of field plants: 2" *lawn, right-of-way

Are there other types of terrestrial habitats present (other than woods, shrub, field/lawn): man made

Observations regarding the presence and/or absence of insects, fish, birds, mammals, etc.? insects observed where seep emerges

Other notes/observations: seep runs across sidewalk into grass

Photo collected? Y / N

Kristi Rieger 5/4/16

CHECKLIST FOR ECOLOGICAL ASSESSMENT / SURFACE WATER SAMPLING

Site Name: 700 S 1600 East PCE Plume

Date: 5/19/16 Time: 0910 Temperature: 53°F Precipitation (24 hr): 0

Surface Water Sample Location: SW-02

Sample location site use description (circle one): residential parcel, commercial parcel, industrial, park, (other: road)

Seep? Y / (N)

Spring? Y / (N)

Pond? Y / (N)

Creek/Stream? Y / (N)

*storm drain

Describe and estimate flow (i.e., barely accumulating seep, spring with noticeably free flowing water, ponded area [depth], creek [width, depth]. : water is moving very quickly - great quantity of water

Describe area immediately surrounding the surface water location. Circle all that apply: mowed lawn, sidewalk, (street,) ornamental planting/garden, wild grass, brush, maintained trees, unmaintained/undisturbed woods, ravine, other. Description: _____

Describe surrounding habitat (within 200 feet of sampling location), circle all that apply: (mowed lawn,) (ornamental planting/garden,) wild grass, brush, sporadic/maintained tree plantings, unmaintained woods, other. Description: street in city

Do any potentially sensitive environmental areas exist adjacent to or in proximity to the site? For example, flood plains, wetlands? Y / (N) Describe: _____

Are there any wooded areas on the parcel? Y / (N.) What percentage of the parcel is wooded? —

What is dominant type of vegetation in wooded area (circle one): NA evergreen / deciduous.
What is predominant size of trees on the parcel (diameter at breast height) (circle one): 0-6 in., 6-12 in., > 12 in.

Is shrub/scrub vegetation present at the parcel? Y / N. What percentage of the parcel is shrub/scrub vegetation? ___—___. Is the shrub/scrub unmaintained (wild) or maintained (circle one). Average height of the shrub/scrub: 0-2ft, 2-2.5 ft, > 5 ft. Is scrub/shrub dense, patchy or sparse (circle one).

Are there open field areas present on the parcel? Y / N. What percentage of the parcel is open field / lawn? ___—___. What is the predominant height of field plants: ___—___

Are there other types of terrestrial habitats present (other than woods, shrub, field/lawn): ___—___

Observations regarding the presence and/or absence of insects, fish, birds, mammals, etc.? _____
No wildlife

Other notes/observations: _____

Describe area immediately surrounding the surface water location. Circle all that apply: (mowed) lawn, (sidewalk), street, ornamental planting/garden, wild grass, brush, maintained trees, unmaintained/undisturbed woods, ravine, (other) Description: seep coming out of retaining wall in backyard. Water collects in small drain

Describe surrounding habitat (within 200 feet of sampling location), circle all that apply: (mowed) lawn, (ornamental planting/garden), wild grass, brush, (sporadic/maintained tree plantings), (unmaintained woods), other. Description: Mowed grass above retaining wall. woods start about 20' to north of seep

Do any potentially sensitive environmental areas exist adjacent to or in proximity to the site? For example, flood plains, wetlands? Y / (N) Describe: _____

Are there any wooded areas on the parcel? (Y) / N. What percentage of the parcel is wooded? 70%

What is dominant type of vegetation in wooded area (circle one): evergreen / deciduous.
What is predominant size of trees on the parcel (diameter at breast height) (circle one): 0-6 in., 6-12 in., > 12 in.

Is shrub/scrub vegetation present at the parcel? Y / N What percentage of the parcel is shrub/scrub vegetation? —. Is the shrub/scrub unmaintained (wild) or maintained (circle one). Average height of the shrub/scrub: 0-2ft, 2-2.5 ft, > 5 ft. Is scrub/shrub dense, patchy or sparse (circle one).

Are there open field areas present on the parcel? Y / N. What percentage of the parcel is open field / lawn? 5%. What is the predominant height of field plants: 1"

Are there other types of terrestrial habitats present (other than woods, shrub, field/lawn): man made (ie. buildings)

Observations regarding the presence and/or absence of insects, fish, birds, mammals, etc.?
Badger lives in woods

Other notes/observations:

Photo collected? Y / N

Describe and estimate flow (i.e., barely accumulating seep, spring with noticeably free flowing water, ponded area [depth], creek [width, depth]. : 5-10 gal/minute

Describe area immediately surrounding the surface water location. Circle all that apply: mowed lawn, sidewalk, street, ornamental planting/garden, wild grass, brush, maintained trees, unmaintained/~~undisturbed~~ woods, ravine, other. Description:

Describe surrounding habitat (within 200 feet of sampling location), ~~circle all that apply~~ mowed lawn, ornamental planting/garden, wild grass, brush, sporadic/maintained tree plantings, unmaintained woods, other. Description:

Do any potentially sensitive environmental areas exist adjacent to or in proximity to the site? For example, flood plains, wetlands? Y / (N) Describe:

Are there any wooded areas on the parcel? Y / (N) What percentage of the parcel is wooded? ___

few trees along road

What is dominant type of vegetation in wooded area (circle one): evergreen / deciduous.
What is predominant size of trees on the parcel (diameter at breast height) (circle one): 0-6 in., 6-12 in., > 12 in.

Is shrub/scrub vegetation present at the parcel? Y / N. What percentage of the parcel is shrub/scrub vegetation? _____. Is the shrub/scrub unmaintained (wild) or maintained (circle one). Average height of the shrub/scrub: 0-2ft, 2-2.5 ft, > 5 ft. Is scrub/shrub dense, patchy or sparse (circle one).

Are there open field areas present on the parcel? Y / N. *lawns, right-of-ways What percentage of the parcel is open field / lawn? 20%. What is the predominant height of field plants: _____

Are there other types of terrestrial habitats present (other than woods, shrub, field/lawn): _____
man made - houses

Observations regarding the presence and/or absence of insects, fish, birds, mammals, etc.? _____
No wildlife observed

Other notes/observations: mitigated spring water

Photo collected? Y / N

Creek/Stream? Y / (N)

Describe and estimate flow (i.e., barely accumulating seep, spring with noticeably free flowing water, ponded area [depth], creek [width, depth]. : water about 6" deep

Describe area immediately surrounding the surface water location. Circle all that apply: mowed lawn, sidewalk, street, ornamental planting/garden, wild grass, brush, maintained trees, unmaintained/undisturbed woods, ravine, other. Description: grass not in contact with storm drain

Describe surrounding habitat (within 200 feet of sampling location), circle all that apply: mowed lawn, ornamental planting/garden, wild grass, brush, sporadic/maintained tree plantings, unmaintained woods, other. Description: residential neighborhood

Do any potentially sensitive environmental areas exist adjacent to or in proximity to the site? For example, flood plains, wetlands? Y / (N) Describe:

Are there any wooded areas on the parcel? Y / (N) What percentage of the parcel is wooded? —

What is dominant type of vegetation in wooded area (circle one): NA evergreen / deciduous.
What is predominant size of trees on the parcel (diameter at breast height) (circle one): 0-6 in., 6-12 in., > 12 in.

Is shrub/scrub vegetation present at the parcel? Y (N) What percentage of the parcel is shrub/scrub vegetation? —. Is the shrub/scrub unmaintained (wild) or maintained (circle one). Average height of the shrub/scrub: 0-2ft, 2-2.5 ft, > 5 ft. Is scrub/shrub dense, patchy or sparse (circle one).

Are there open field areas present on the parcel? (Y) N. What percentage of the parcel is open field / lawn? 55%. What is the predominant height of field plants: 1"

Are there other types of terrestrial habitats present (other than woods, shrub, field/lawn): man made structures

Observations regarding the presence and/or absence of insects, fish, birds, mammals, etc.? No wildlife observed

Other notes/observations:

CHECKLIST FOR ECOLOGICAL ASSESSMENT / SURFACE WATER SAMPLING

Site Name: 700 S 1600 East PCE Plume
Date: 5/2/16 Time: 1410 Temperature: 65 Precipitation (24 hr): 0
Surface Water Sample Location: SW-42

Sample location site use description (circle one): residential parcel, commercial parcel, industrial, park, other: _____

Seep? (Y) / N
Spring? Y / (N)
Pond? Y / (N)
Creek/Stream? Y / (N)

Describe and estimate flow (i.e., ~~barely accumulating~~ seep, spring with noticeably free flowing water, ponded area [depth], creek [width, depth]. : _____

Describe area immediately surrounding the surface water location. ~~Circle all that apply~~: mowed lawn, sidewalk, street, ornamental planting/garden, wild grass, brush, ~~maintained~~ trees, unmaintained/undisturbed woods, ravine, other. Description: _____

Describe surrounding habitat (within 200 feet of sampling location), circle all that apply: mowed lawn, ornamental planting/garden, wild grass, brush, sporadic/maintained tree plantings, unmaintained woods, other. Description: _____

Do any potentially sensitive environmental areas exist adjacent to or in proximity to the site? For example, flood plains, wetlands? Y / (N) Describe: _____

Are there any wooded areas on the parcel? (Y) / N. What percentage of the parcel is wooded? 10%

What is dominant type of vegetation in wooded area (circle one): evergreen / deciduous.
What is predominant size of trees on the parcel (diameter at breast height) (circle one): 0-6 in., 6-12 in., > 12 in.

Is shrub/scrub vegetation present at the parcel? Y / N. What percentage of the parcel is shrub/scrub vegetation? 40%. Is the shrub/scrub ~~unmaintained~~ (wild) or maintained (circle one). Average height of the shrub/scrub: 0-2ft, 2-2.5 ft, > 5 ft. Is scrub/~~shrub~~ dense, patchy or sparse (circle one). ivy in between

Are there open field areas present on the parcel? Y / N. What percentage of the parcel is open field / lawn? 0%. What is the predominant height of field plants: _____

Are there other types of terrestrial habitats present (other than woods, shrub, field/lawn): No

Observations regarding the presence and/or absence of insects, fish, birds, mammals, etc.? some mosquitoes

Other notes/observations: Seep is channelized into concrete lined ditch

1.0 Introduction and Background

This report presents the analytical results from the 2016 vapor intrusion (VI) investigation for Accelerated Operable Unit 1 East Side Springs (AOU 1), which is part of the 700 South 1600 East Tetrachloroethene (PCE) Plume. This report is being submitted on behalf of the U.S. Department of Veterans Affairs (VA) Salt Lake City Health Care System, which is working cooperatively with the U.S. Environmental Protection Agency (EPA) and the Utah Department of Environmental Quality (UDEQ) to implement the remedial investigation (RI). The VI investigation results included in this report supplement the indoor air and soil gas sampling performed in 2015. The 2015 sampling was guided by the RI Work Plan (First Environment [FE] 2015), which included the sampling and analysis plan and quality assurance project plan attachments. The data collection activities briefly described in this report are based on those detailed in the *2016 VI Sampling Plan for Accelerated Operable Unit 1: 700 South 1600 East PCE Plume Technical Memorandum, Salt Lake City, Utah* (sampling plan) (EA Engineering, Science, and Technology, Inc., PBC [EA] 2015). The results of these data collection activities will help VA refine the conceptual site model describing the nature, extent, fate, and transport of PCE associated with the PCE plume, specifically with respect to the potential for impacts to indoor air through the subsurface-to-indoor-air VI pathway.

AOU 1 is located in Salt Lake City, Salt Lake County, Utah, along the Wasatch Fault scarp within the general residential area bounded by 500 South and Michigan Avenue between 1300 East and 1100 East (Figure 1). In 2010, chlorinated volatile organic compounds (VOCs), including PCE and trichloroethene (TCE), were detected in the surface water associated with seeps and springs along the fault in AOU 1. The location of the seeps and springs near residences and other occupied structures and the shallow depth to groundwater suggested the potential for VI into occupied spaces. AOU 1 is defined as the area where springs are known to have PCE contamination and where groundwater is within 50 feet of the ground surface, and includes a 100-foot buffer around that area.

THIS PAGE INTENTIONALLY LEFT BLANK

2.0 Summary of Previous Characterization Activities

VA began collecting site-specific VI data within AOU 1 (FE 2015) in January 2015. More than 1,000 soil gas and indoor air data points were collected from 35 structures consisting of private residences, schools, a church, and an elder-care facility. The structures represent a cross section of structure types, construction dates, depths to groundwater, and locations within AOU 1. The analytical results from those samples were used to update the conceptual site model for AOU 1, which in turn was used to identify data gaps and to prepare a sampling plan (EA 2015) to fill those data gaps.

3.0 Summary of 2016 Characterization Activities

This section presents a summary of and rationale for the additional VI sampling activities conducted within AOU 1 from February 2016 to June 2016. Further detail regarding 2016 VI sampling activities can be found in the RI Work Plan (FE 2015) and sampling plan (EA 2015). Sampling 11 new (that is, not previously sampled as part of the 2015 effort) and five previously sampled structures in an area with higher potential for VI was proposed following the 2015 effort. In addition, indoor air samples were collected from three structures and analyzed by EPA Method TO-15 (EPA 1999) to confirm that vinyl chloride is not present. Details for each of these objectives are provided in the following subsections.

3.1 Focus Area for 2016 Sampling

The VI data collected in 2015 pointed to a portion of AOU 1 with a higher potential for VI to result in indoor air concentrations above risk-based screening levels (RBSLs). These data, combined with AOU 1 hydrogeological data, facilitated the delineation of a focus area for the 2016 VI sampling (Figure 2). In 2016, ten residential and one public structure (East High School) within this focus area underwent individual VI investigation. The locations of these structures are shown on Figure 2. Collection of additional VI data from these structures within this focus area was conducted to support preparation of the RI report, including refining the conceptual model of VI within AOU 1, evaluating potential risk, and helping focus future monitoring.

3.2 Locations and Methods

The following three sampling goals outlined in the RI Work Plan were to be satisfied with the additional 2016 sampling:

- Sampling indoor air with EPA Method TO-15 analysis at five previously sampled structures to assess temporal variability in potentially VI-related indoor air PCE concentrations

- Sampling 11 new (not previously sampled) structures within the focus area to assess spatial variability. This included screening indoor air and near-slab soil gas using a portable gas chromatograph/mass spectrometer called a INFICON HAPSITE® (HAPSITE). EPA Method TO-15 analysis of both indoor air and soil gas was also specified in the event an RBSL exceedance occurred during HAPSITE indoor air screening

- Collecting a limited number of indoor air samples to confirm the absence of vinyl chloride.

EPA Method TO-15 samples were analyzed for PCE, TCE, cis-1,2-dichloroethene (DCE), vinyl chloride, and 1,4-dioxane. HAPSITE samples were analyzed for PCE, TCE, and cis-1,2-DCE. The following subsections describe the locations and methods for each sampling goal.

3.2.1 Previously Sampled Structures

The goal of resampling structures was to assess temporal variability of indoor air and VI-related VOC concentrations. The three residences where PCE was detected above the residential screening levels were selected for this purpose because potential VI had been identified. In addition, the two residences where elevated PCE concentrations were detected in uninhabited breathing space in association with groundwater collection sumps were selected to provide information about variability where potential

vapor sources exist within the structure, but previous results were nondetect or below screening levels in the habitable areas.

Sampling at these structures consisted of 24-hour SUMMA™ canister samples of indoor air for EPA Method TO-15 analysis. Other components of the VI protocol (FE 2015), such as the HAPSITE data collection and detailed building surveys, were not repeated. An abbreviated interview and building survey was performed to identify major changes that could affect the sampling and data evaluation (recent remodels or changed basement moisture conditions, for example). Table 1 lists the numbers and types of samples collected at these five structures.

3.2.2 New Structures

The goal of sampling structures not previously sampled during 2015 was to gain a better understanding of the spatial extent of VI-related impacts associated with AOU 1 groundwater. The additional structures within the focus area are identified on Figure 2 and in Table 1. One of the targeted structures was East High School. The remainder were residences. The VI protocol (FE 2015) guided the data collection at these structures. This included HAPSITE screening of indoor air and near-slab soil gas and EPA Method TO-15 analysis of both indoor air and soil gas if screening levels were exceeded during HAPSITE screening of indoor air and soil gas.

Following the collection of additional information about the building layout and use, three individual rooms within East High School were selected for sampling following the VI protocol considering the following factors:

- Proximity to PCE-impacted groundwater: The available site information was evaluated to identify the portions of the building where the vadose zone is thinnest and which are closer to the approximate inferred axis of the PCE plume. These criteria were chosen to bias the samples to those zones nearest the highest vapor source strength and the smallest degree of subsurface vapor attenuation.

- Room characteristics: Smaller rooms were preferred over larger rooms because the air available for mixing and dilution in smaller rooms is less than in larger rooms. Only occupied or potentially habitable rooms were considered.

Table 1 shows the numbers and types of samples collected at East High School and the previously unsampled residences. Figure 2 shows the locations of East High School and the 10 sampled residences within the focus area.

3.2.3 Vinyl Chloride Nondetect Confirmation Sampling

During the 2015 indoor air and near-structure soil gas screening process, the field team discovered that the HAPSITE portable gas chromatograph/mass spectrometer was unable to reliably quantify vinyl chloride at concentrations below the 5 parts per billion by volume calibration level, which was greater than the RBSL (0.17 micrograms per cubic meter [$\mu g/m^3$]). Vinyl chloride was subsequently removed from the HAPSITE's calibration procedure (see Appendix L of the RI Work Plan [FE 2015]). EPA requested that the following four additional EPA Method TO-15 indoor air samples be collected from structures where two criteria were met:

- One sample outside the plume where PCE, TCE, and cis-1,2-DCE in the indoor air were below the RBSLs or the detection limit of the HAPSITE instrument.

- Three samples inside the area of the plume where PCE and TCE were equal to or less than their respective RBSLs, but above the instrument detection limits.

Sampling conducted at structure 0003-H in November 2015 satisfies the first requirement. Structures satisfying the second requirement are listed in Table 1.

THIS PAGE INTENTIONALLY LEFT BLANK

4.0 Results

The findings from the 2016 sampling are summarized in the following subsections. This section is divided into subsections based on the data collection activities outlined in Section 3 (previously sampled structures, new structures, and vinyl chloride nondetect confirmation sampling). Analytical results are compared to RBSLs and removal action levels (RALs) presented in Table 2.

4.1 Previously Sampled Structures

Table 3 contains the analytical results for the confirmation EPA Method TO-15 samples collected at 0003-H, 0011-H, 0017-H, 0018-H, 0023-H, and 0037-H. These samples were 24-hour indoor air samples collected in 6-liter SUMMA canisters that had been individually laboratory-certified clean. Each sample was analyzed using EPA Method TO-15. Validated analytical results are provided in Appendix A-1, laboratory data reports are in Appendix A-2, and laboratory sample receipt notifications are in Appendix A-3.

4.2 New Structures

The following subsections present the analytical results of the HAPSITE survey/pressure cycling along with sample location and sample condition descriptions for the 11 new structures sampled in 2016 (0040-H, 0041-H, 0045-S, 0047-H, 0050-H, 0051-H, 0052-H, 0053-H, 0054-H, 0055-H, and 0056-H). HAPSITE calibration reports are included in Appendix B and are organized by calibration date. HAPSITE calibration parameters were within the specifications defined in the RI Work Plan (FE 2015).

4.2.1 0040-H

The VI investigation at 0040-H was conducted on March 10, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 pascals [Pa]) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 4 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

Indoor air concentrations of PCE and TCE exceeded their respective residential indoor air RBSLs and Tier 1 RALs in the northwest basement bedroom under baseline condition (that is, no building pressure manipulation) (Table 4). The indoor air PCE and TCE concentrations exceeded their respective RBSL during both negative pressure steps of the pressure cycling event at this structure (Table 4).

As specified in the VI protocol (FE, 2015), follow-up 24-hour indoor air EPA Method TO-15 samples were collected due to the residential indoor air screening level and removal action level exceedances on March 10, 2016. Three indoor air EPA Method TO-15 samples were collected at this structure on March 12, 2016: a parent and a field duplicate sample were collected from the northwest basement bedroom, and one sample was collected from the main level kitchen. Table 5 presents the analytical results for these samples. PCE was detected above the Tier 1 RAL in the kitchen and basement samples.

PCE was detected below the soil gas RBSL in the near-slab soil gas (Table 4).

4.2.2 0041-H

The VI investigation at 0041-H was conducted on March 9, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 6 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs during the HAPSITE survey and pressure cycling event at this structure (Table 6). No indoor air samples were collected for EPA Method TO-15 analysis.

PCE was not detected in the near-slab soil gas (Table 6).

4.2.3 0047-H

The VI investigation at 0047-H was conducted on February 25, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 7 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs during the HAPSITE survey and pressure cycling event at this structure. No indoor air samples were collected for EPA Method TO-15 analysis.

PCE was detected below the soil gas RBSL in the near-slab soil gas (Table 7).

4.2.4 0050-H

The VI investigation at 0050-H was conducted on March 23, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. No target analytes exceeded indoor air RBSLs or RALs during the HAPSITE survey and pressure cycling event at this structure (Table 8).

TCE and PCE were detected in the near-slab soil gas below their respective soil gas RBSLs (Table 8). No indoor air samples were collected for EPA Method TO-15 analysis.

On May 2, 2018 the sample identification numbers for 0050-H in Table 8 were updated as they were mislabeled in the September 2016 final version of this report. Previously, the location identifier (i.e., 0050H-) for each sample identification number used 0051H as the location identifier rather than 0050H. This mislabeling has been corrected in this version of the report and has no affect on the report results.

4.2.5 0051-H

The VI investigation at 0051-H was conducted on February 26, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 9 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

Indoor air concentrations of PCE exceeded the PCE noncancer residential indoor air RBSL (11 µg/m^3) during both depressurization steps in the basement mechanical room (uninhabited space) (Table 9). PCE was not detected in indoor air during pressurization.

As specified in the VI protocol (FE 2015), follow-up 24-hour indoor air EPA Method TO-15 samples were collected due the residential indoor air RBSL exceedances on February 26, 2016. One parent and one field-duplicate EPA Method TO-15 sample were collected at this structure on March 16, 2016. Both samples were collected in the basement living room. Table 5 contains the analytical results of these samples. PCE was detected below the residential RBSL in these samples.

PCE was detected at a concentration below the residential soil gas RBSL in the near-slab soil gas (Table 9).

4.2.6 0052-H

The VI investigation at 0052-H was conducted on March 11, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 10 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure. No target analytes exceeded indoor air RBSLs or RALs during the HAPSITE survey and pressure cycling event at this structure. No indoor air samples were collected for EPA Method TO-15 analysis.

PCE was detected at a concentrations below the residential soil gas RBSL in the near-slab soil gas (Table 10).

4.2.7 0053-H

The VI investigation at 0053-H was conducted on May 2, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 11 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

Indoor air concentrations of PCE exceeded the residential indoor air RBSL during baseline sampling (HAPSITE survey), depressurization, and pressurization in the basement living room (Table 11). Indoor air PCE concentration decreased below the residential indoor air RBSL during pressurization (Table 11).

As specified in the VI protocol (FE 2015), follow-up 24-hour indoor air EPA Method TO-15 samples were collected due to the residential indoor air RBSL exceedances. One parent sample and one field duplicate indoor air EPA Method TO-15 sample were collected in the basement living room on May 24, 2016. Table 5 contains the analytical results of these samples. PCE was detected slightly above the residential RBSL but below the residential RAL in both samples.

Both TCE and PCE near-slab soil gas concentrations exceed their respective noncancer residential soil gas screening levels on May 2, 2016. As specified in the VI protocol (FE 2015), 5-minute soil gas EPA Method TO-15 samples were collected due to this residential soil gas RBSL exceedance. Two soil gas EPA Method TO-15 samples were collected at this structure on May 24, 2016. Both samples were collected from 6 feet below ground surface and 1 foot from the north exterior wall of the residence.

Table 5 contains the analytical results of these samples. PCE and TCE were detected above their respective residential soil gas RBSLs in the EPA Method TO-15 soil gas samples.

4.2.8 0054-H

Two VI investigations were conducted at 0054-H. These events took place on May 9, 2016, and June 3, 2016. These two investigations were needed due to detections of VOCs in and around a centrally located shop in the residence basement, which contained numerous chemical products. The initial investigation data suggested the presence of interior background sources in the shop. However, the number of items stored within this space made positively identifying a specific interior background source impractical. Additionally, the resident informed the sampling team that motorcycle and bicycle maintenance had historically taken place within this space. VA requested that the resident remove shop items before additional sampling could be performed. The resident was able to remove the majority of the shop items, and additional sampling was conducted on June 3, 2016. The following summarizes the result of the two sampling events at this structure.

May 9, 2016. The initial VI investigation at 0054-H was conducted on May 9, 2016. During baseline sampling, indoor air TCE concentrations throughout the residence exceeded the residential indoor air Tier 1 RAL. Indoor air TCE and PCE concentrations were highest in the shop (Table 12).

Only the initial depressurization of -5 Pa was completed on May 9, 2016, as the HAPSITE became inoperable. TCE indoor air concentrations remained near the residential indoor air RAL during the depressurization at -5 Pa (Table 12).

No near-slab soil gas sample was collected on May 9, 2016.

Following this first VI investigation, VA requested that the resident remove all items stored in the shop before a second VI investigation could be conducted.

June 3, 2016. The second VI investigation was conducted on June 3, 2016. Baseline TCE and PCE indoor air concentrations were lower throughout the residence than those measured on May 9, 2016. During baseline sampling, TCE indoor air concentrations in the basement exceeded the TCE RAL (2.2 µg/m^3), and PCE was detected below the RBSL in the basement (Table 13). No interior background sources were identified within the residence during the HAPSITE survey.

The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 13 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure. Indoor air TCE concentrations in the shop decreased during depressurization and remained steady during pressurization. The indoor air PCE concentration in the shop slightly increased during depressurization and was nondetect by the end of pressurization (Table 13).

TCE was not detected in near-slab soil gas, and PCE was detected at a concentrations below the residential soil gas RBSL in the near-slab soil gas (Table 13).

No 24-hour indoor air EPA Method TO-15 samples were collected at this structure as the data suggested that indoor air TCE concentrations resulted from an interior background source(s) or residual TCE from historical activities in the shop.

4.2.9 0055-H

The VI investigation at 0055-H was conducted on May 13, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 14 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded their respective indoor air RBSLs or RALs during the HAPSITE survey and pressure cycling event at this structure. No indoor air samples were collected for EPA Method TO-15 analysis.

TCE and PCE were not detected in the near-slab soil gas (Table 14).

4.2.10 0056-H

The VI investigation at 0055-H was conducted on May 3, 2016. No interior background sources were identified within the residence during the HAPSITE survey. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 15 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded their respective indoor air RBSLs or RALs during the HAPSITE survey and pressure cycling event at this structure. No indoor air samples were collected for EPA Method TO-15 analysis.

PCE was detected below its residential soil gas RBSL in near-slab soil gas (Table 15).

4.2.11 0045-S

The VI investigation at 0045-S (East High School) was completed in three individual sampling events: (1) HAPSITE survey (March 4, 2016), (2) first pressure cycling (March 21, 2016), and (3) second pressure cycling (March 22, 2016). The following paragraphs summarize the results of these sampling events.

HAPSITE Survey. Multiple indoor samples were collected and analyzed on the four levels of 0045-S during the HAPSITE survey. During this sampling event, effort was taken to achieve adequate spatial coverage on each level during sampling. TCE and PCE were detected only in the auto shop in the southwest corner of the main level (ground level), where interior sources of TCE and PCE (for example, brake cleaner) were positively identified in a chemical storage closet within the auto shop. The auto shop was the only location where target analytes were detected during the HAPSITE survey. The analytical results of the HAPSITE survey are presented in Table 16. No 24-hour indoor air EPA Method TO-15 samples were collected at this structure as the data suggested that TCE and PCE concentrations in indoor air resulted from an interior background source(s) or residual TCE from historical activities in the auto shop.

Pressure Cycling. Pressure cycling was conducted within three separate compartments: Room A203/ A205 and Room A213 on March 21, 2016 (first pressure cycling event), and Room A215 on March 22, 2016 (second event). These compartments are on the ground level toward the southwest area of 0045-S. The following summarizes the pressure cycling results for each compartment.

Room A203/A205. No interior background sources were identified within Room A203/A205 prior to pressure cycling. The three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. No target analytes were detected during the pressure cycling event at this location (Table 17). No indoor air samples were collected for EPA Method TO-15 analysis.

Room A213. No interior background sources were identified within Room A213 prior to pressure cycling. Only depressurization was achieved at this location because the sampling team was asked to leave so the facilities manager could set alarms and lock the building. Approximately 2.5 air volumes were exchanged during each depressurization step. No target analytes were detected during the pressure cycling event at this location (Table 18). No indoor air samples were collected for EPA Method TO-15 analysis.

Room A215. No interior background sources were identified within Room A215 prior to pressure cycling. The baseline differential pressure within Room A215 was -5 Pa prior to pressure cycling. Therefore, the three differential pressures targeted for this event were -10, -15, and 5 Pa, which were achieved. Approximately 2.5 air volumes were exchanged during each pressure step. No target analytes exceeded indoor air RBSLs or RALs during the pressure cycling event at this location (Table 19). No indoor air samples were collected for EPA Method TO-15 analysis.

4.2.12 Additional Information

Field notes were scribed in a spiral-bound Rite-in-the-Rain–type notebook during the 2016 sampling events. A scanned copy of the field notes is included in Appendix C. Chain-of-custody forms for the EPA Method TO-15 samples collected during the 2016 sampling events are included in Appendix D. Appendix E contains the native HAPSITE data reports for each sampled location.

4.3 Vinyl Chloride Nondetect Confirmation Sampling

Vinyl chloride was not detected at the three locations selected to confirm the absence of vinyl chloride. The analytical results for these three locations are presented in Table 3.

4.4 Deviations from Remedial Investigation Work Plan

During the 2016 VI investigative work, there was one deviation from the RI Work Plan (FE 2015) (from the Sampling and Analysis Plan [SAP], Appendix A of the RI Work Plan [FE 2015]). This deviation was regarding the sample naming convention outlined in SAP Table 3. This naming convention was not followed during 2016 VI sampling, although a similar sample naming convention was followed.

TABLE 7
0047-H HAPSITE Analytical Results
700 South 1600 East PCE Plume AOU 1: East Side Springs, 2016 Vapor Intrusion Investigation Field Data Report, Salt Lake City VA Medical Center, Utah

NOTES:
µg/m^3 = Microgram(s) per cubic meter.
' = Feet.
< = Less than.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
bgs = Below ground surface.
BL = Baseline.
ft = Feet (foot).
IA = Indoor air.
IASL = Residential indoor air screening level.
ID = Identification.
N5 = Negative 5 Pascal pressure step.
N10 = Negative 10 Pascal pressure step.
NA = Not applicable.
OA = Outdoor air.
P5 = Positive 5 Pascal pressure step.
PCE = Tetrachloroethene.
RAL = Residential removal action level.
SG = Soil gas.
SW = Southwest.
VA = Department of Veterans Affairs.

Bolded values are detections.

NOTES:

µg/m^3 = Microgram(s) per cubic meter.

' = Feet.

< = Less than.

AOU 1 = Accelerated Operable Unit 1 East Side Springs.

bgs = Below ground surface.

BL = Baseline.

ft = Feet(foot).

IA = Indoor air.

IASL = Residential indoor air screening level.

ID = Identification.

N5 = Negative 5 Pascal pressure step.

N10 = Negative 10 Pascal pressure step.

NA = Not applicable.

OA = Outdoor air.

P5 = Positive 5 Pascal pressure step.

PCE = Tetrachloroethene.

RAL = Residential removal action level.

SG = Soil gas.

VA = Department of Veterans Affairs.

Bolded values are detections.

Shaded values are screening level and/or removal action level exceedances.

NOTES:

µg/m^3 = Microgram(s) per cubic meter.

' = Feet.

< = Less than.

AOU 1 = Accelerated Operable Unit 1 East Side Springs.

bgs = Below ground surface.

BL = Baseline.

ft = Feet(foot).

IA = Indoor air.

IASL = Commercial/industrial indoor air screening level.

ID = Identification.

N10 = Negative 10 Pascal pressure step.

N15 = Negative 15 Pascal pressure step.

NA = Not applicable.

OA = Outdoor air.

P5 = Positive 5 Pascal pressure step.

PCE = Tetrachloroethene.

SG = Soil gas.

RAL = Commercial/industrial removal action level.

VA = Department of Veterans Affairs.

Bolded values are detections.

Shaded values are screening level and/or removal action level exceedances.

FULL SCAN Calibration Response Table

HAPSITE method: /Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth

Method Description:

SIM CVOC Method in order of elution VC; 1,1-DCE; trans-DCE; 1,1-DCA; cis-DCE; CtCl; TCE; PCE

General Quantification Range from 0.1 ppbv to 50 ppbv

Tune File: default.tun

Target Library: QB 24FEB2016

Last Modified: 2/24/2016 6:54:40 PM

W = RT +- (0:08.00 / 2 + RT * 0.050)

Min Fit = 0.200; Min Pur = 0.200; Min Area = 5000

Width = 7 - 70 scans; Res = 5 scans; NLM = 2.000

Average Response Factor

Internal Standards

Analytes

Analyte. #1 -- 1,1-DCE

Pressure Cycling

1/3

QGB
CH

2/24/16

1800 Calibrated VA HAPSITE. Calibrate meet requirements.
Range 0.1 - 10 ppbv
1900 Ran 5 ppbv calibration verification. (Run #12
CIS = 5.3 ppbv TCE = 5.5 ppbv PCE = 5.5 ppbv
CV passed. QC CV => RPD must be ≥ 70%

END

QGB
CH

2/25/16

0650 Arrived @ SLC office. Began loading equipment.
Printed PTSP. Filled out PTSP.
0720 Chris + Quan signed PTSP + AHA.
0810 Arrived @ 0047-H. Discussed sampling ~~pr~~ approach.
0825 Resident allowed entrance explained VI assessment process. Jeremy Laird on-site
0845 Residents left for work.
0850 Began initial HAPSITE survey.
1010 Mechanical room has > PCE detection (1.3 ppbv). Surveyed various products in the mechanical room. No products indicated that they contain PCE. Moving forward w/ Pressure cycling.

Est. House Air Volume = 19,200 ft3

1100 Mark from EPA/Denver on-site. Jeremy showed him around the site.
1121 Began PC set up. Omniguard installed in basement laundry room window; westside. Set to log every 5 min in pascals.
Omniguard Serial # = G405318 (Pine Environmental Rental)
Initial ΔP = -0.5 Pa
Omniguard Job Name = 47H
Chris Holt recording ΔPs and operating blower door.
Blower door install in back door (north side). Door located @ ground level
1145 David Waite onsite.

1155 Began -5 Pa pressure step.

(Continue) H.G. Bingham

1210 David Waite + Jeremy Laird left site.

- 5 Pa Pressure Cycle

Avg Flow rate = ~586 CFM
2.5 Air exchange = 77 minutes
Total Air Volume = ~~45,000~~ 18,000 ft3
Avg Δ Pressure = -5.1 Pa

1315 Increased negative pressure to -10 Pa for one set of samples (mechanical Room, near blower door, upstairs living room)

-10 Pa Pressure Cycle

Avg flow rate = 925 CFM
2.5 Air Exchanges = 77.1 minutes
Total Air Volume = 18,000 ft3 (house volume)
Avg Δ Pressure = -10.1 Pa

1405 Ended -10 Pa PC

1410 Began +5 Pa PC
1440 Jeremy Laird back on-site.

+5 Pa PC

Avg flow rate = 705 CFM
2.5 Air exchange =
Avg Δ Pressure = 5.1 Pa
Total Air Volum = 18,000 ft3 (house volume)

1505 Ended +5 Pa PC. Ran 5 ppbv CCl4. Began packing equipment. Re-installed furnace covers. ~~Relit~~ Lite water heater pilot light.

5 ppbv CCl4 CIS = 88% RPD
TCE = 96% RPD
PCE = 96% RPD

1610 Left site.

0051-H
Pressure Cycling

2/26/16 QGTB
CH

0745 Arrived @ SLC office. Set up field sample log spreadsheet. Set up HAPSITE.

0810 Loaded vehicle w/ equipment + MOB to 0051-H.

0845 Arrived @ 0051-H. Filled out PTSP.

0900 Chris Holt on-site. Both signed PTSP.

0910 Began HAPSITE survey. No interior VOC sources identified.

0930 Jeremy Laird on-site.

0940 EA + Cascade drilling onsite out front for direct push groundwater sampling.

0956 Nick Kirkham on-site

1010 Began equipment setup for pressure cycling. PCE concentrations on all 3 levels ~~[illegible]~~ were the same (0.3 ppbv). Basement mechanical room w/ floor drain and bare concrete floors was 0.55 ppbv. No interior products found in home. Large floor crack located in mechanical room.

→ Omniguard installed in east basement window. Job name 51H. Logging every 5 min.

→ Blower door install in back door (south side) at top of stairs to the basement. (ground level). Recorded baseline differential pressure.

→ Baseline $\Delta P = -1.5$ Pa

1035 Chris began recording baseline pressure reading. See baseline reading above.

1043 Began -5 PC. Set ΔP @ -6.5 Pa since baseline was -1.5 Pa.

1059 Chris left to collect SG samples @ 0047-H

	time	ΔP Door (Pa)	ΔP Omni (Pa)	Q (cfm)
-5 Pa	11:15	-6.2	-6.5	932
	11:40	-6.4	-6.5	925
	11:55	-6.2	-6.5	930
-10 Pa	1212	-11.7	-11.5	1430
	1220	-11.3	-11.5	1420

* Canister 0084 Lealy initial P on 2/29/16 was -20 inHg and -0.1 inHg on 3/3/16 w/out being used.

0045-S EHS
Initial HAPSITE SURVEY

3/4/16

QGB

0600 Arrived @ SCC office. Edited HAPSITE method to only analyze for CIS 12DCE, TCE, PCE. Re-calibrated since higher std concentration of CIS were higher than desired (5 ppbv std = CIS was 6.2 ppbv).
A404C Loaded equipment in field vehicle.
Calibration looked good. all analytes met required RSD, RSD of RF, and R^2.

Ran 5 ppbv calibration verification before MOB to EHS. CV passed (all RPDs ≥ 70%)

0810 Arrived @ EHS Meet w/ Jeremy Laird & Marcus (EHS facility manager).

0820 Began sampling Level A (Ground/basement level) Ground level on westside // Basement level on eastside

1020 Brake Cleaner w/ PCE identified w/in Autoshop. Chemical storage closet in autoshop clearly had PCE/TCE containing materials. PCE = 5.5 ppbv TCE = 16 ppbv w/in closet. Brake cleaner labeling PCE found in closet. Other products were not surveyed due to lack of time.

1040 Probe seems to be contaminated w/ PCE. ~~Perhaps~~ may be due to survey PCE containing PCE. Turned probe temperature up to 80°C or method ran various runs to clean out.

1045 Terence Mares dropped off extra sample probe from KD Analytical HAPSITE to replace contaminate probe.
Installed new probe and ran multiple samples. PCE concentrations steadily declining

1423 Ran 0.5 ppbv CCV to check calibration. TCE + CIS passed.
PCE slightly above 130% RPD @ 134%.
Proceeded w/ sampling.

0045-5
Pressure Cycling

3/21/16

0630 Ran CCA (5 ppbv). cis, TCE, PCE RPD= 88%, 92%, 106% respectively.
0700 Filled out coc for 03/16/16 TO-15 samples.
0730 Rachel arrived @ office. Began loading equipment

0830 Arrived @ 0045-5. Jeremy Loisel on-site. Jeremy provided us w/ additional Nitrogen cylinder
0906 Filled out Pre-task, baseline sampling
0910 Outdoor air sample

0945 Set up blower door in Room A203/A205
~~Volume Room A203/A205=29,700 ft³~~
0955 Take front Lobby Sample (between pillars) 20160321_005

1006 Take sample @ south end of front hallway

1020 Start negative pressure cycling to -5.0 (config A1)
Avg Q= 1208 CFM Avg DP= -5.2 Pa
1159 Began -10 Pa PC.
Avg Q= 2466 CFM Avg DP= -10.1 Pa
Room A203 + A205 are one room. Biology lab w/ ~15 ft ceilings ~~East~~ East wall is an exterior wall with windows but windows are designed not to open. Room has two entrances on the west wall. One on the north and one on south end of classroom. No VOC containing products identified in this space

1350 Ended +5 Pa PC in Room A203/A205 / Avg Q= 1501 / Avg DP= 4.4 Pa
1355 Move to Room A213
1400 Collected IA sample from Room A219 (woodshop)
1405 Began set up for PCing on Room A213. Volume = 14,880 ft³
No interior sources in Room A213.
1500 Begin negative cycle to -5 PA
Avg Q= 1349 CFM Avg DP= -5.4 Pa
1535 Begin negative cycle to -10 PA
Avg Q= 1743 CFM Avg DP= -10.2 Pa

Rite in the Rain.

0054-H

5/18/11

Personnel: QGB
Objective: HAPSITE survey at residence to confirm interior source.
Equipment: HAPSITE, field tools, AMS soil gas sampling kit
Weather: Sunny 68°F

0800 Began HAPSITE calibration. ~~Range 0.1-10 ppbv~~ (QB) Ran 5 ppbv calibration check on SPM 100PPB-VA_20160513 and it passed. No calibration required.

0915 Loaded equipment and MOB to 0054-H.

1000 Arrived @ 0054-H. Resident met us outside the home and expressed how sampling today would not be possible since her father just had a stroke, her husband just had emergency back surgery. She also expressed concern about actually having any additional sampling completed. Jeremy and I expressed our understanding and left under the understanding we would follow up soon.

1030 MOB to VA office. Had conference call w/ Novak and VA to discuss pathforward.
Jeremy spoke w/ resident. They agreed to do the sampling today

1130 On-site w/ Jeremy Laird and Lynne Welsh. Jeremy mentioned to me that she intended to remove everything from shop area (expected compartment w/ indoor source) in the next two weeks. I explain to Lynne and Jeremy that it would be ~~good~~ better to sample after cleaning out the shop area. ~~[illegible]~~ Sampling after shop area is cleaned will provide more informative data.
Jeremy called and left a VM w/ the wife and spoke w/ the husband regarding this pathforward. He agreed to it. Jeremy plans to send email explaining the pathforward.

1200 MOB to SLC office

0053-H

5/23/16

Personal QGB, Jeremy Laird
Objective: deploy 2 6-L Summas w/ basement and collect soil gas samples for TO-15 analysis
Weather: 65°F Sunny
Equipment: Summas, AMS soil gas test, field tools
1000 Loaded equipment into field vehicle.
1050 Arrived @ 0053-H
1053 Jeremy Laird on-site.
1100 Allowed entrance into residence.
Set up two 6-L Summa is basement mean room. 24hr samples.

INDOOR AIR SAMPLES

Canister ID: 0050 FC ID: not used
IP: -25.50 inHg FP -5.47 inHg
Start time: 12:15 End time: 12:15
Date: 5/23/16

★ One liter purged prior to sample collection. Lung box used to purge + collect sample. 1-liter tedlar bag filled then placed on summa to transfer. This was required since ~~[illegible]~~ required to collect sample

Rite in the Rain

OU3-11

Soil Gas Samples 5/23/16

⇒ The two summa soil gas samples were not true splits. One liter of soil gas was purged prior to each summa collection. Each sample was collected in a Tedlar bag and then evacuated into a summa.

12:30 Scheduled to return on 5/24/16 @ 0830 to pick up 24-hr Summas deployed in basement

0054-H

6/3/16

Personnel: QGB, RA, Jeremy Laird
Objective: Pressure cycle residence
Equipment: HAPSITE, Omniguard, blower door, field tool
Weather: Sunny 70°F

0800 Arrived @ office. Loaded equipment into field vehicle.
0 HAPSITE calibrated on 6/2/16. Calibration range 0.1–10 ppbv. Method: STM-~~[illegible]~~PPB-VA-080216 CCV (5ppbv) passed.

0830 MO3 to 0054-H.

0915 Arrived @ 0054-H.

0930 Jeremy Laird arrived @ 0054-H. Allowed entrance to residence. Resident requested that he not be bothered during PCing. He is in separate basement room.
Shop in basement has plastic covering slated doors to the shop. Resident claimed everything has been removed from shop. Removed 2 days ago.
Shop area indicated potential indoor source last sampling round. Hence this sampling event.

1000 Installed Omniguard IV in basement bathroom window (Northside)

1125 −5 Pa PC began. Blower installed upstairs in back entrance door

1304 −10 Pa PC began

1455 +5 Pa PC began

~~[illegible]~~ (3) 1630 Ended +5 Pa PC.

1640 Collected soil gas sample on north side of residence near basement laundry room windows. Collected from approximately 7 ft bgs. Purged 2-L and analyzed 3rd liter.

1700 Left residence.

Window Expand Factor: 0.050
Peak Resolution: 5
Noise Level Multiplier: 2.000
Minimum Area: 5000
Minimum Width: 7
Maximum Width: 70
Minimum Fit: 0.200
Minimum Purity: 0.200

Q-Ion	Pred.RT	Analyte Name	Act.RT	fit	purity	area	ppb	Flag
61	02:00.6	cis-1,2 DCE	01:56.9	0.934	1	24141	0.011	
130	02:38.1	TCE	02:32.5	0.905	1	51671	0.018	
166	03:38.9	PCE	03:39.1	0.994	1	6285	0.002	

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs
cVOC = Chlorinated volatile organic compound.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

LOCATION: 0041-H
SAMPLE DATE: 8-Mar-16

Unknown Identification Report
Date: 03/14/16 Time: 14:37:38
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

Data File: C:\Users\qbingham\Documents\1_Projects\2_VA AOU1\0041-H\HAPSITE\Data\SIM_100PPB_VA_20160304_20160307_003.hps

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
cVOC = Chlorinated volatile organic compound.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

LOCATION: 0045-S HAPSITE SURVEY
SAMPLE DATE: 4-Mar-16

Unknown Identification Report
Date: 03/08/16 Time: 12:38:11
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

LOCATION: 0045-S PRESSURE CYCLING ROOM A203/A205
SAMPLE DATE: 21-Mar-16
Unknown Identification Report
Date: 03/21/16 Time: 15:51:23
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

LOCATION: 0045-S PRESSURE CYCLING ROOM A213
SAMPLE DATE: 21-Mar-16

Unknown Identification Report
Date: 03/21/16 Time: 16:57:44
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

LOCATION: 0045-S PRESSURE CYCLING ROOM A215
SAMPLE DATE: 22-Mar-16

Unknown Identification Report
Date: 03/23/16 Time: 06:55:39
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
cVOC = Chlorinated volatile organic compound.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

LOCATION: 0047-H HAPSITE SURVEY
SAMPLE DATE: 25-Feb-16

Unknown Identification Report
Date: 02/25/16 Time: 16:43:08
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution VC;
1,1-DCE; trans-DCE; 1,1-DCA; cis-DCE;
CtCl; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
CtCl = Carbon tetrachloride.
cVOC = Chlorinated volatile organic compound.
DCA = Dichloroethane.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.
VC = Vinyl chloride.

LOCATION: 0050-H HAPSITE SURVEY
SAMPLE DATE: 23-Mar-16

Unknown Identification Report
Date: 03/23/16 Time: 13:18:41
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
cVOC = Chlorinated volatile organic compound.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
CtCl = Carbon tetrachloride.
cVOC = Chlorinated volatile organic compound.
DCA = Dichloroethane.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.
VC = Vinyl chloride.

LOCATION: 0052-H HAPSITE SURVEY
SAMPLE DATE: 11-Mar-16

Unknown Identification Report
Date: 03/11/16 Time: 16:29:46
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs
cVOC = Chlorinated volatile organic compound
cis-1,2 DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

LOCATION: 0053-H HAPSITE SURVEY
SAMPLE DATE: 2-May-16

Unknown Identification Report
Date: 05/03/16 Time: 07:26:20
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
cVOC = Chlorinated volatile organic compound.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

LOCATION: 0054-H HAPSITE SURVEY
SAMPLE DATE: 9-May-16

Unknown Identification Report
Date: 05/10/16 Time: 13:33:32
Calibration Method:
/Haps/Method/Analyze/Concentrator/Hill Vapor Intrusion Cal 2 min SIM.mth
Tune File:
default.tun
Method Description:
SIM cVOC Method in order of elution
cis-DCE; TCE; PCE
General Quantification Range from 0.1
ppbv to 50 ppbv

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
cVOC = Chlorinated volatile organic compound.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

NOTES:
Act. = Actual.
AOU 1 = Accelerated Operable Unit 1 East Side Springs.
cVOC = Chlorinated volatile organic compound.
DCE = Dichloroethene.
PCE = Tetrachloroethene.
ppb = Part(s) per billion.
ppbv = Part(s) per billion per volume.
Pred. = Predicted.
RT = Retention time.
TCE = Trichloroethene.
VA = Department of Veteran Affairs.

TECHNICAL MEMORANDUM

TO: Lynne Welsh, Department of Veterans Affairs

FROM: George Tangalos, EA Team (EA Engineering, Science, and Technology, Inc., PBC/ CH2M HILL)

DATE: 28 February 2017

SUBJECT: Conceptual Site Model Update for the 700 South 1600 East PCE Plume AOU-1: East Side Springs, Salt Lake City, Utah

1. Introduction

1.1 Objective

The purpose of this Conceptual Site Model (CSM) update is to support further development of the Remedial Investigation (RI) strategy for the 700 South 1600 East Tetrachloroethene (PCE) plume (the Site) by integrating information from previous source investigations; existing groundwater data; and available geological, hydrogeological, and modelling data. The CSM will be used to identify data gaps in knowledge about the Site, which will directly inform the scoping process for the RI and feasibility study process. This CSM is an update of the CSM prepared in 2015 (First Environmental [FE], 2015).

1.2 Site Investigation History

The Site is located near the Wasatch Mountain front in the northeastern corner of the Salt Lake Valley (Figure 1). The Site was first identified in 1990 during sampling and analysis of the Mt. Olivet irrigation well. The concentration of PCE in groundwater from the Mt. Olivet well was 32 parts per billion (ppb) at that time. In 1997, PCE was initially detected at Salt Lake City Department of Public Utilities (SLCDPU) Drinking Water Well No. 18 (SLC-18) at a concentration of 0.6 ppb, and the PCE concentration in the Mt. Olivet irrigation well had increased to 184 ppb. In 1998, the United States Environmental Protection Agency (EPA) conducted additional investigations of the area and installed seven monitoring wells (EPA-MW-01S, EPA-MW-01D, EPA-MW-02, EPA-MW-03, EPA-MW-04, EPA-MW-05, and EPA-MW-06) east of the Mt. Olivet well (Utah Department of Environmental Quality [UDEQ], 2000) (Figure 2 and Table 1). During this investigation, source areas for the PCE contamination and the extent of the plume were not clearly identified. However, a sewer line originating from a former dry-cleaning facility at the Veterans Administration (VA) Medical Center was identified as a potential source (Bowen Collins 2004) (Figure 2).

In 2010, in response to an oil pipeline break near Red Butte Creek, water samples were collected by the SLCDPU from Red Butte Creek and springs and seeps emanating along the Wasatch Fault scarp west of 1300 East (i.e., the East Side Springs area). PCE was detected in several of these springs and seeps. Since 2010, additional investigations have been performed to investigate potential source areas and the nature and extent of PCE contamination (UDEQ 2012; MWH 2012). These investigations have resulted in the identification of several possible source areas, as discussed in this technical memorandum.

In September 2012, EPA released the hazard ranking for the Site (EPA 2012). In May 2013, EPA listed the Site on the National Priorities List, making the Site eligible for comprehensive assessment and cleanup through the Comprehensive Environmental Response, Compensation and Liability Act or Superfund process (EPA 2014).

In early 2016, groundwater, surface water (including storm water), soil, soil gas, and indoor air samples were collected and analyzed to support the ongoing RI for Accelerated Operable Unit 1 (AOU-1) in the East Side Springs area (EA 2016a), as well as this CSM update.

1.2.1 Potential Source Areas

Several investigations have been performed in the past, including groundwater, soil, and soil-gas sampling, but a definitive source area has not been identified for the PCE plume. Based on historical records (EPA 2012), as well as data from previous investigations (IHI Environmental 2005, 2007; UDEQ 2000, 2012), three potential source areas have been identified: the VA Medical Center, Building 7; a former Utah Army National Guard vehicle maintenance facility; and a former United States Forest Service (USFS) Helicopter Pad (Figure 2).

VA Medical Center Building 7 (Former Dry Cleaning Facility)

A sewer line (Figure 3) associated with a former dry-cleaning facility at the VA Medical Center Building 7 has been identified as the likely source area, despite limited and inconclusive groundwater, soil, and soil-gas data (UDEQ 2012).

During routine cleaning of the sanitary sewer line near the VA Medical Center Building 7 in the early 1980s, employees of the SLCDPU documented discolored water and odors of drycleaner solvent (EPA 2012).

In November 1996, a soil-gas sample was collected near the southeast corner of Building 6 at the VA Medical Center; this soil-gas sample contained 1.9 ppb of PCE (UDEQ 2000). This location is near the loading dock area of Building 7.

A video survey of the sewer line between Building 7 and Sunnyside Avenue, conducted in December 2003 by SLCDPU, documented numerous defects including cracks, root penetrations, offsets and a pipe sag, as well as evidence of historic breaks, repairs, and replacements of the clay pipe (EPA 2012).

In 2007, the VA contracted a soil gas investigation along the sanitary sewer line lateral beginning at Building 7 and running south to Sunnyside Avenue (Figure 3) (IHI 2007). During the investigation, 48 passive soil gas samplers were installed along the sewer line. PCE was detected in four of the 48 samples; three of which were collected adjacent to the loading dock area of Building 7 and had PCE ranging from 34 to 90 nanograms. However, soil sampling performed in 2004, which happened before the correlative soil gas investigation in 2007, detected no affected soils at the Building 7 loading dock location (IHI 2005).

Former Utah Army National Guard Vehicle Maintenance Facility

The former Utah Army National Guard vehicle maintenance facility was located east of the Mt. Olivet Cemetery. According to UDEQ (2000), 15 soil-gas samples from the area surrounding the facility were collected in 1995. Only two contained chlorinated solvents: one sample collected near the Mt. Olivet

Cemetery contained 16 ppb of PCE, and one sample collected near the former Utah Army National Guard vehicle maintenance building contained 1 ppb of TCE.

Former United States Forest Service Helicopter Pad

To support interagency fire-fighting efforts, the USFS maintained a helicopter pad near the northeast corner of the intersection of Sunnyside Avenue and Guardsman Way. This site is no longer in use by the USFS and has been converted to a University of Utah softball field. This site has not been previously investigated as a potential source area, and any reclamation efforts associated with the termination of use of the helicopter pad are unknown.

2. Ground and Surface Water Monitoring Network

The existing monitoring locations include monitoring wells, drinking water and irrigation wells, artesian wells, seeps and springs, and surface water. Details about each of these monitoring network components are described below.

2.1 Groundwater

2.1.1 Monitoring Wells

A total of eight monitoring wells (MW-01S, MW-01D, MW-02, MW-03, MW-04, MW-05, MW-05R, and MW-06) have been installed during past investigations of the PCE plume. MW-03 was abandoned due to building construction within 1 year of its installation. In 2016, MW-05 was destroyed but replaced in the same location with MW-05R in September of 2016. Information on the existing groundwater monitoring well network is summarized on Table 1. The well data were compiled from the MWH (2012), UDEQ (2012), and UDEQ (2000) reports, and the MW-05R boring log (Attachment A).

2.1.2 Temporary Piezometers

To assess the nature and extent of the 700 South 1600 East PCE Plume and to characterize vapor intrusion potential, temporary small-diameter groundwater monitoring points were installed throughout the East Side Springs area (Figure 4) (EA 2016a). While 34 of the groundwater monitoring points were abandoned immediately after sampling, ten temporary monitoring points were left in place as piezometers to enable future groundwater sampling. Information on the remaining 10 piezometer points is summarized on Table 2.

2.1.3 Drinking Water and Irrigation Wells

Information on the municipal drinking water wells (no longer in service) and irrigation wells in the vicinity of the VA Medical Center well monitoring network is also provided in Table 1. The well data were compiled from the MWH (2012), UDEQ (2012), and UDEQ (2000) reports.

2.1.4 Artesian Wells

Existing artesian (flowing) wells are identified on Table 3; these well are located in the Salt Lake Valley, several miles hydraulically downgradient of the Site (Figure 2). The artesian conditions documented at these wells indicate that confined aquifer conditions are present in the Salt Lake Valley. The location identifications are from the UDEQ (2012) report.

2.2 Surface Water

2.2.1 Red Butte Creek

The headwaters of Red Butte Creek are located in the Wasatch Mountains. As Red Butte Creek exits the Wasatch Mountains through Red Butte Canyon, it enters the Salt Lake Valley and flows through developed business and residential areas (Figure 2). Surface exposure of Red Butte Creek terminates east of Liberty Park, and the creek is diverted underground. Water from Red Butte Creek is assumed to be connected to the Liberty Park Reservoir.

2.2.2 Mt. Olivet Reservoir

The Mt. Olivet Reservoir is located in the Mt. Olivet Cemetery near the northeast corner of the cemetery adjacent to 500 South (Figure 2). The reservoir is supplied by diversions from both Red Butte Creek and Emigration Creek (via a diversion to Red Butte Creek) and the Mt. Olivet Cemetery Irrigation Well (Per. Comm., 2014).

2.2.3 Liberty Park Pond

The Liberty Park Pond is located in Liberty Park, Salt Lake City (Figure 2). The pond is supplied by diversions from Red Butte Creek. In June of 2010, an oil pipeline rupture impacted Red Butte Creek, which in turn impacted the Liberty Park Pond. This resulted in the draining, dredging, and cleaning of the pond.

2.2.4 Seeps and Springs

Seeps and springs in the area are located on residential, public, and private properties containing numerous homes, several public and private schools, a large public park, and several churches. Following the 2010 release of crude oil from a pipeline, Salt Lake City identified 25 springs along the Wasatch Fault line in the area between 800 South and Michigan Avenue (approximately 1300 South) and between 1100 East and 1300 East (UDEQ 2012). During the investigation, although constituents of crude oil were not identified, PCE was detected in several springs and surface water sources (UDEQ 2012). The data from the UDEQ (2012) report was used to develop the investigation area for the East Side Springs, as well as contour preliminary plume shapes where PCE contamination may be present. These preliminary plume shapes are used in the CSM figures to illustrate the East Side Springs area (with the exception of Figure 4; the Figure 4 plume contours are based on 2016 data collected as part of the ongoing RI for AOU-1).

Following the UDEQ (2012) report, the SLCDPU compiled of a more comprehensive list of identified springs and seeps along the East Bench segment of the Wasatch Fault (Attachment B); this list was used as a basis for the 2016 surface water investigation (Figure 5) (EA 2016a).

The ESS-SW identification nomenclature is for springs identified and sampled by UDEQ (2012) (Figure 2); the SP identification nomenclature is for springs identified and sampled by UDEQ (2000) (Figure 2); and the SW-00 identification nomenclature is for springs, seeps and storm water identified by the VA (EA, 2016a) (Figure 5). The data for seeps and springs that have been sampled are summarized in Table 4.

2.2.5 Storm Water Run-off

Several seeps and springs in AOU-1 are mitigated and discharged to storm water lines; therefore, Salt Lake City storm water sewer manholes, located in and downgradient of AOU-1, have been sampled (EA 2016a). Stormwater sample locations consisted of mitigated spring water storm drains, storm water lines, and the Jordan and Salt Lake City Canal. The storm water sampling locations are shown on Figure 5.

3. Geology

3.1 Geologic Setting

The Salt Lake Valley, located in the northern part of Utah, is an alluvial basin bounded by the Wasatch Range to the east, the Oquirrh Mountains to the west, the Traverse Mountains to the south, and the Great Salt Lake to the north-northwest. The Salt Lake Valley is within the Basin and Range Physiographic Province, which is characterized by generally parallel, north-to northeast-trending mountain ranges separated by broad alluvial basins that are a result of Cenozoic-age extensional faulting. The Wasatch Range, formed by uplift along the Wasatch Fault, defines the eastern boundary of the Basin and Range.

The consolidated rocks in the Wasatch Range bounding the northeastern part of Salt Lake Valley, from Emigration Canyon northward to Dry Creek Canyon, are predominantly the Jurassic-age Twin Creek Limestone, the Triassic-age Nugget Sandstone, Ankareh Formation (sandstone, shale and mudstone), the Thaynes Formation (limestone, interbedded with sandstone and shale), the Permian Park City Formation (limestone and shale), and Weber Quartzite (Davis, 1983). These faulted and folded units maintain bedding planes striking approximately perpendicular to the mountain front (Thiros 2010).

The basin-fill deposits in the Salt Lake Valley consist of unconsolidated to semi-consolidated Tertiary-age deposits overlain by unconsolidated Quaternary-age deposits. Based on geophysical studies by Mattick (1970), the contact between the basin-fill deposits and underlying consolidated bedrock near the center of the valley is estimated to be as deep as 4,000 feet (ft) below land surface.

The VA Medical Center is located on unconsolidated sediments of Quaternary age that were deposited mainly as alluvial fans, by streams, and as deltas and other lacustrine features associated with Lake Bonneville and older paleo-lakes that once filled the valley (Thiros 2010). In general, sediments deposited near the mountain front (i.e., the location of the VA Medical Center) tend to be coarser-grained gravels and sands with no substantial, laterally continuous layers of fine-grained materials.

3.2 The Wasatch Fault

The Salt Lake Valley alluvial basin is bounded on the east by the Wasatch Fault, which is comprised of several seismically-independent segments that have been active in Holocene time. This active fault zone has uplifted the Wasatch Mountains as much as 7,000 ft relative to the valley (Thiros 2010).

The East Bench Fault segment of the Wasatch Fault runs predominately north-south, just west and approximately parallel to 1300 East in Salt Lake City. The surface expression of the fault scarp is apparent between approximately 1300 East and 1100 East. Personius and Scott (2009) mapped a spur of the East Bench Fault segment of the Wasatch Fault that strikes northeasterly in the vicinity of SLC-18 (Figure 6).

3.3 Site Lithology

The surficial geology changes from east to west across the 700 South 1600 East PCE plume site. Near the VA Medical Center, the surficial geology is comprised of coarse-grained alluvial fan deposits of gravel in a matrix of sand and silty sand, surrounded by lacustrine deposits to the south, west, and north. Generally, the lacustrine deposits become more fine-grained to the west of the Site, until the East Bench Fault (Personius and Scott, 2009). The East Bench Fault is defined by the presence of mixed colluvium and alluvium deposited as a debris apron at the base of the fault's scarp (Personius and Scott, 2009). The sediments underlying the Site are hundreds of ft thick; bedrock is assumed to be located at a depth exceeding 1,000 ft below ground surface (bgs).

Boring logs for the EPA monitoring wells are presented in the UDEQ (2000) report. These logs include depths of lithologic contacts, soil descriptions, and soil classifications. The logs also contain well construction data and measured depths to groundwater. The logs show that although several small lenses of fine-grained materials occur near the Site, the predominant lithology is coarser grained alluvial material.

Lithologic data for the Mt. Olivet Well and SLC-18 are available in the Utah Division of Water Rights (UDWRi) records (Water Right No. 57-2526 and 57-101/57-4413, respectively) (UDWRi, 2014) and summarized in the UDEQ (2000) and MWH (2012) reports. For these older water-supply wells, the data are limited to lithologic contact depths, soil descriptions, and some well construction details. Although the wells produce water from multiple screened intervals, the logs provide little information of value with respect to aquitard and aquifer intervals.

From 2004 to 2005, and 2015 to 2016, the United States Geological Survey (USGS) conducted groundwater studies using the EPA monitoring wells, Mt. Olivet irrigation well, and SLC-18. These investigations used downhole geophysical tools to evaluate the lithology at the monitoring well locations, with an objective of using the geophysical data to correlate lithology between wells. Through the geophysical analysis, as well as the sediment type and moisture content of specified intervals documented in the boring logs, the USGS identified a series of shallow aquifers and aquitards and hypothesized the presence of a northwest-dipping clay layer at approximately 180.0 ft bgs (USGS 2005). In recent discussions with the USGS (Per. Comm., 2014), the presence and nature of this clay-layer is an interpretation based on limited data; however, the 2015 and 2016 geophysical data may serve to validate or repudiate the previous hypothesis. The data collected in 2015 and 2016 are not yet available to the public.

Several additional boring logs were identified in UDWRi records, including an abandoned 1,004-foot exploratory borehole on VA property (Water Right No. 1057004M00), and an abandoned 1,508-foot-deep exploratory borehole on University of Utah property (Water Right No. 0757007M00 and 0657008M00) (Figure 2). The abandoned exploratory borehole on the University of Utah property encountered bedrock at approximately 280.0 ft bgs, while the abandoned borehole on the VA property did not encounter bedrock (Attachment C).

Lithology from available boring logs and surficial geology descriptions provided by the Personius and Scott (2009) were used to develop a generalized cross-section, shown in Figure 7, and block diagram, shown in Figure 8. The sediment lithology characterized in the boring logs is coarse- to fine-grained upper-basin fill consisting of gravel, sand, silty sand, clay lenses, and interbedded sequences of the aforementioned sediment types. Upper-basin fill sediments are typical of the Wasatch Front and are primarily unconsolidated Quaternary-age deposits, deposited mainly as alluvial fans by streams, and as deltas and other lacustrine features associated with Lake Bonneville and older paleolakes that once filled

the valley (Thiros 2010). Drilling in the East Side Springs area during the ongoing AOU-1 RI was limited to 50 ft bgs, and did not change the current understanding of the regional lithology.

3.4 Surface Topography

The Site is located in a developed urban area. The topography of the area slopes to the southwest at a grade of approximately 4 percent until reaching the East Bench segment of the Wasatch Fault scarp, where it steepens to approximately 10 percent (EPA 2012). The ground surface elevation at the VA Medical Center is approximately 4,735 feet above mean sea level (amsl); the approximate elevation of 1300 East, which runs parallel to the Wasatch Fault scarp, is 4,530 ft amsl; and the elevation of Artesian Well Park is approximately 4,266 ft amsl. The fault scarp is the defining topographic feature shown on Figure 9.

4. Hydrogeology

4.1 Hydrostratigraphy

Groundwater in the Salt Lake Valley occurs in basin-fill sediments that can be divided into four aquifers (Waddell et al. 1987; Thiros 2003):

1. Local, unconfined perched aquifers
2. A deep unconfined aquifer between the artesian aquifer and the mountains
3. A shallow unconfined aquifer overlying the artesian aquifer
4. A deep confined (artesian) aquifer

The localized, unconfined perched aquifers are located near the Wasatch Mountains. Groundwater from the unconfined perched aquifers can move downward into the deep unconfined aquifer because the perched aquifers are discontinuous and lack substantial layers of fine-grained materials. The unconfined perched aquifers transition laterally to form the shallow unconfined aquifer to the west, away from the mountain front. As groundwater in the deep unconfined aquifer flows towards the center of the Salt Lake Valley, it becomes confined beneath laterally continuous fine-grained layers to form the deep confined (artesian) aquifer. The artesian or flowing wells at Liberty Park and Artesian Park tap this deep confined aquifer.

The basin-fill deposits are very complex because they consist of multiple aquifers and confining layers that are both laterally discontinuous and internally heterogeneous; however, all the unconsolidated water-bearing materials in the valley are connected hydraulically to some degree (Waddell 1987). Combined, the deep confined aquifer and the deep unconfined aquifer form the principal aquifer that most groundwater wells in the Salt Lake Valley utilize (Wallace and Lowe, 2009).

4.2 Primary and Secondary Recharge Zones

The primary recharge area for the basin-fill aquifers is near the mountain fronts and associated fault zones where no continuous layers of fine-grained material that will impede the downward movement of water are present (Thiros 2003).

Secondary recharge occurs where continuous layers of fine-grained material are thin or completely absent, and water flows through shallow basin-fill alluvial sediments (i.e., perched aquifers) into deeper basin-fill sediments (i.e., deep unconfined aquifer). The secondary recharge zone borders the primary recharge area on the west and includes the area of the East Side Springs (Figures 7 and 8).

The VA Medical Center and the 700 South 1600 East PCE Plume are within both primary and secondary recharge areas, based on boundaries defined by the USGS (Thiros 2010). SLC-18 and the Mt. Olivet irrigation well are both located in the primary recharge area (Anderson, *et al* 1994; Bowen Collins 2004). The SLC-18 well log indicates "clay and gravel are present to a depth of 266 ft, but does not indicate there are significant clay layers in the area that would impede the downward migration of water or contamination to the aquifer (Bowen Collins 2004)."

4.3 Groundwater Levels and Potentiometric Surfaces

The depth-to-groundwater in the unconfined part of the shallow unconfined basin-fill aquifer (i.e., along the mountain fronts) is typically from 150.0 to 200.0 ft bgs (Thiros 2010). The depth-to-groundwater in the deep confined aquifer ranges from 100.0 to 140.0 ft bgs in the secondary recharge area along the mountain front, to only 1.0 to 5.0 ft bgs in the discharge areas in the center of the valley as a result of the lower surface elevations (Thiros 2010).

The most recent water level data for the EPA monitoring wells, SLC-18, and the Fountain of Ute (Table 1) were presented in the EA (2016b) and FE (2014) reports. The EPA-MW-03 well was abandoned during construction of the Salt Lake City Sports Complex; as such, the water level presented for this well is from the UDEQ (2000) report and was measured just after well construction. The FE (2014) and EA (2016b) reports do not provide water levels for the Mt. Olivet Well (i.e., permission not granted) and University of Utah Well 1 (U of U #1) (i.e., actively pumping); however, the EA (2016b) report does provide water quality data for both wells.

Thorough and consistent historical time-series water level records for these wells are not available; however, Table 5 summarizes the known water level record. The USGS National Water Information System (NWIS) maintains water level records for active (e.g., Bonneville Golf Course Well; Fountain of Ute) and inactive (e.g., SLC-18) wells across the State of Utah; these records are available through the USGS NWIS website (USGS 2014). These records, while of general use on a regional scale, are generally not useful for tracking small scale changes or localized effects on water levels.

Based on the available data, two potentiometric surfaces can be defined by the existing groundwater monitoring well network (Figure 10). An upper potentiometric surface, representative of the shallow part of the unconfined aquifer, can be preliminarily defined by monitoring wells EPA-MW-01S, EPA-MW-02, EPA-MW-03 (abandoned), EPA-MW-04, and EPA-MW-05. The approximate elevation of this upper potentiometric surface near the VA Medical Center is 4,522 ft amsl. A lower potentiometric surface, representative of deeper parts of the unconfined aquifer, can be preliminarily defined by EPA-MW-01D, SLC-18, and the Fountain of Ute. The approximate elevation of this lower potentiometric surface near the VA Medical Center is 4,489 ft amsl. The potentiometric elevations of the nested wells EPA-MW-01S and EPA-MW-01D are approximately 16 ft in difference, indicating a relatively strong vertical hydraulic gradient of approximately 0.09 ft/ft (Table 1), as would be expected in a primary recharge area.

4.4 Horizontal Hydraulic Gradients and Flow Directions

The potentiometric surface for the basin-fill aquifer indicates that groundwater generally moves from recharge areas near the Wasatch Mountain front toward the Jordan River and the Great Salt Lake. In the northeastern part of the Salt Lake Valley, and in the vicinity of the VA Medical Center, groundwater generally flows from the northeast to the southwest (Thiros 2010).

Contrarily, using data obtained from groundwater monitoring wells during a 1999 field investigation (UDEQ 2000), EPA concluded that groundwater flow near the VA Medical Center is toward the northwest. However, MWH (2012) and Bowen Collins (2004) surmised that the northwest groundwater flow direction is representative of "perched and localized mounding in the shallow portion of the shallow unconfined aquifer, and the regional groundwater flow direction is from the northeast to the southwest." However, without better evidence of a perching unit (i.e., a laterally continuous clay or silt layer), it seems unlikely that perched conditions are present based on available boring logs.

As described above, two potentiometric surfaces were contoured: one for shallow groundwater (e.g., the shallowest part of the unconfined aquifer), and a second for deeper groundwater (e.g., the deeper part of the unconfined aquifer) (Figure 10). Shallow groundwater, represented by the "upper potentiometric surface" flows to the northwest, while the somewhat deeper groundwater represented by the "lower potentiometric surface" flows to the west-northwest. A preliminary horizontal hydraulic gradient calculation for the upper potentiometric surface, based on the difference in groundwater elevations and the distance between EPA-MW-05 and the spring ESS-SW-17 (118 ft, and 5,800 ft, respectively) is 0.02 ft/ft. A preliminary horizontal hydraulic gradient calculation for the lower potentiometric surface, based on the difference in groundwater elevations and the distance between SLC-18 and the Fountain of Ute (6 ft, and 1,400 ft, respectively) is 0.004 ft/ft.

Distortion in the upper potentiometric contours may be related to groundwater pumping from the U of U #1 well, or could be due to surveying errors or simply the limited groundwater elevation dataset. The lower potentiometric flow direction is based on simple interpolation from only three water level elevations; as more water elevation data from wells screen in this depth interval become available, the flow direction could change appreciably. As it stands now, the flow direction for groundwater in the lower zone appears to be influenced by groundwater pumping from the U of U #1 well, which operates at night during the summer and early fall months.

4.5 Horizontal Hydraulic Conductivity and Transmissivity

Regional hydraulic conductivity values from 0.03 feet/day (ft/d), to as much as 3,000 ft/d, with a log-normalized mean value of 30 ft/d have been reported for coarse-grained basin-fill deposits in the Basin and Range province (Thiros 2003). Numerical modelling conducted by Lambert (1995) for regional Salt Lake Valley groundwater flow conditions, as cited in Thiros (2010), estimates the hydraulic conductivity for coarser grained deposits in the shallow unconfined aquifer of the Salt Lake Valley to be about 200 ft/d. In contrast, Lambert's estimate of hydraulic conductivity for fine-grain lake-deposited clays, characteristic of the shallow unconfined aquifer in the center of the Salt Lake Valley, was about 1 ft/d.

The transmissivity (i.e., hydraulic conductivity multiplied by the saturated thickness of the aquifer) of the shallow unconfined aquifer ranges from 50 to 4,000 feet squared per day (ft^2/d) and the storage coefficient is estimated to average 0.15 (Wallace and Lowe, 2009). Locally, a 30-day pump test at SLC-18 and a slug test at EPA-MW-01D yielded estimated transmissivities for the shallow unconfined aquifer of 22,700 to 35,800 ft^2/d, respectively, with hydraulic conductivities ranging from 45 ft/d to 140 ft/d (MWH 2012). The local transmissivity values are an order of magnitude greater than the average transmissivity values for the shallow unconfined aquifer; however, Thiros (2010) notes that transmissivity is generally highest near the mountains where streams entering the valley deposit the coarsest-grained materials.

Transmissivity and storage coefficients (a dimensionless number representing the volume of water an aquifer releases from or takes into storage per unit surface area of the aquifer per unit change in head)

range from 1,000 to 50,000 ft^2/d and 0.15 to less than 0.0001, respectively, for the two values, for the unconfined and confined parts of the principal (deep) aquifer, respectively (Wallace and Lowe, 2009).

4.6 Groundwater Velocity

Preliminary estimates of groundwater velocity for the unconfined aquifer range from 0.6 ft/d to 1.9 ft/d. This groundwater velocity estimate is based on an assumed sediment porosity of 0.3; the hydraulic conductivities (45 ft/d to 140 ft/d) of the unconfined aquifer measured during aquifer pump testing at SLC-18 and slug testing at EPA-MW-01D (MWH 2012); and the horizontal hydraulic gradient (0.004 ft/ft) calculated for the lower potentiometric surface.

4.7 Vertical Hydraulic Conductivity

Groundwater moves downward in the primary and secondary recharge areas, from the source to the shallow unconfined aquifer, and ultimately to the deeper principal basin-fill aquifers. In locations where the shallow unconfined aquifer is present, where fine-grained deposits are present, vertical hydraulic conductivity values range from 0.01 to 1 ft/d (Thiros 2003). The vertical hydraulic conductivity of the confining bed between the shallow unconfined and principal aquifer is estimated to average 0.025 ft/d (Wallace and Lowe, 2009).

4.8 Effects of Wasatch Fault on Groundwater Flow

MWH (2012) performed aquifer testing of SLC-18, and concluded that the East Bench Fault Spur, which has been mapped adjacent to SLC-18 (Personius and Scott, 2009), is not a barrier to groundwater flow. This interpretation is the result of a strong response recorded at the EPA-MW-01D well, which indicated a hydraulic connection between the wells (MWH 2012). The presence of PCE in springs and seeps downgradient of the fault further suggests that the East Bench Fault Spur is not a flow barrier.

5. Water Quality and Geochemistry

The shallow unconfined aquifer, and where present, the unconfined part of the deep principal aquifer are susceptible to contamination from activities related to land use because of its proximity to the land surface, and because it is generally comprised of coarse-grained sediments with high hydraulic conductivity values that enable rapid movement of contaminants from the surface to the water table. Water quality in the confined deep aquifer can be degraded by secondary recharge of contaminated water from the unconfined shallow and deep aquifers.

5.1 Water Quality

The chemical composition of groundwater in the Salt Lake Valley varies with location and depth, primarily due to quality of recharge sources and water-rock interactions as it moves from recharge to discharge areas.

5.1.1 Groundwater

Groundwater in the unconfined shallow aquifer in the northeastern part of the Salt Lake Valley generally has more dissolved sulfate relative to bicarbonate compared to upgradient source water (Thiros 2010). Total-dissolved-solids (TDS) concentrations in the shallow unconfined aquifer are generally greater than 500 milligrams per Liter (mg/L), primarily as a result of water-rock interactions with easily eroded

Triassic-age shale and mudstone (e.g., Ankareh Formation) in the mountain block and in the basin-fill deposits of the area (Thiros 2010).

Based on maps presented in Wallace and Lowe (2009), groundwater in the vicinity of the Site would be classified as Class II – Drinking Water Quality Groundwater (TDS between 500 and 3,000 mg/L [UDEQ 2014]). TDS concentrations in the Salt Lake Valley basin-fill aquifer range from 512 to 2,588 mg/L (Wallace and Lowe, 2009). Concentrations of dissolved oxygen in groundwater in the Salt Lake Valley range from 0.3 to 11.6 mg/L, and pH ranges from 6.8 to 8.0 standard units (Thiros 2010). Groundwater in the Salt Lake Valley is generally oxic and neutral pH.

Thiros (2010) provides groundwater quality summary data for different parts of the Salt Lake Valley. For the east side of the Salt Lake Valley, Thiros (2010) states the following:

- Groundwater sampled from wells (5 wells) in the deeper unconfined basin-fill aquifer in the primary recharge area contain modern water; and median pH of 7.1, 7.4 mg/L dissolved oxygen, and 562 mg/L TDS concentrations.

- Groundwater sampled from wells (11 wells) in the shallow unconfined basin-fill aquifer in the secondary recharge area contain modern water; and a median pH of 7.3, 5.3 mg/L dissolved oxygen, and 414 mg/L TDS concentrations.

- Groundwater sampled from wells (15 wells) in the deeper confined basin-fill aquifer in the secondary recharge area contain modern and mixed-age waters; and median pH of 7.5, 5.8 mg/L dissolved oxygen, and 316 mg/L TDS concentrations.

The EA (2016b) report provides Site data (Table 6) congruent with data for the greater Salt Lake Valley. The data indicate that groundwater in the vicinity of the Site is aerobic and neutral in pH. The EA (2016a) report provides shallow groundwater quality measurements for the AOU-1 area (Table 7). The water quality results of shallow groundwater near the Wasatch Fault scarp are more variable than deeper groundwater near the Site. While the pH of the AOU-1 shallow groundwater is neutral, the groundwater quality ranges from anoxic to oxic (0.25 mg/L to 4.77 mg/L), and is generally reducing (-3.3 millivolts [mV] to 121.5 mV).

5.2 Contaminant Distribution

PCE and daughter products in deep groundwater near the VA Medical Center have been identified in monitoring wells (EPA wells), an irrigation well (Mt. Olivet Well), and a municipal drinking water well (SLC-18) downgradient and cross-gradient of the VA Medical Center (Table 5 and Figure 11). The potential width of the deep groundwater plume, as defined by the distance between SLC-18 and EPA-MW-06, is approximately 3,000 ft. The potential length of the plume, as defined by the distance between the upgradient well EPA-MW-05 and the East Side Springs (ESS-GW-07), is approximately 6,000 ft. Along the East Bench segment of the Wasatch Fault, which runs parallel to 1300 East in Salt Lake City, PCE and daughter products have been detected in springs and seeps emerging from the fault scarp (Figure 2), as well as in shallow groundwater (Table 8 and Figure 4). This East Side Springs area currently defines the toe of the PCE plume. Although PCE and daughter products have not been detected in the artesian wells at Artesian and Liberty Parks, it is unknown if any chlorinated ethene-contaminated groundwater has flowed through or under the fault area.

PCE has been detected at depths ranging from 130.0 ft bgs (4,549 ft amsl) at EPA-MW-06, down to 470.0 ft bgs (screened from 4,408 to 4,204 ft amsl) at SLC-18. The Mt. Olivet irrigation well is screened at a lower elevation, but the well contains multiple screened intervals (from 4,167 to 4,230 ft amsl; from 4,253

to 4,350 ft amsl; from 4,395 to 4,415 ft amsl; and from 4,435 to 4,455 ft amsl) in the same well casing; as such, it is unknown at what depth contamination is entering the well.

As previously discussed, the PCE source area is not well defined and PCE contamination may have originated from one or more source areas. The sanitary sewer line extending from VA Medical Center Building 7 to Sunnyside Avenue (Figure 3) has been considered a likely source area (EPA 2012), but the soil and soil gas data previously collected along this sewer line have not revealed a definitive source area or "hot spot."

5.2.1 PCE Concentration Data

Based on water levels, the EPA wells (except EPA-MW-01D) are likely screened in the upper part of the shallow unconfined aquifer. The PCE concentrations in this shallow zone have ranged from 0.8 to 320 micrograms per Liter (µg/L), with a maximum concentration of 320 µg/L observed at EPA-MW-01S in November 1998. PCE has not been detected in the upgradient background well (EPA-MW-05) since installation. The most recent maximum concentration for this upper zone was 72 µg/L in July of 2016 at EPA-MW-02 (Table 5).

Based on water levels, the EPA-MW-01D monitoring well, the Mt. Olivet irrigation well, and the SLC-18 drinking water well are likely screened in a deeper part of the unconfined aquifer. The PCE concentrations in this lower zone have ranged from non-detect to 184 µg/L, with a maximum historical concentration of 184 µg/L observed at the Mt. Olivet irrigation well in 1997. The most recent maximum concentrations for this deeper zone were 40 µg/L at the Mt. Olivet irrigation well in May 2016, and 9.1 µg/L at the EPA-MW-01D in April 2016 (Table 5).

In the East Side Springs area, the maximum concentration of PCE in shallow groundwater (i.e., less than 50 ft bgs was 52 µg/L measured at piezometer GW-52 in July 2016 (Table 8). The concentration of PCE measured in springs, seeps and surface water in the East Side Springs area have not yet been reported from the 2016 AOU-1 RI; historically, the maximum concertation of PCE in springs and seeps was 40.4 µg/L at ESS-SW-15 (as known as SW-11) in August 2010 (Table 4)

Statistical interpretation of PCE concentration trends has not been completed at this time. However, based on visual data observations, PCE concentrations in wells of the shallow zone (EPA-MW-01S, EPA-MW-02, EPA-MW-04, EPA-MW-06) appear to be lower than when the wells were first installed whereas PCE concentrations in the wells of the deeper zone (EPA-MW-01D, SLC-18, Mt. Olivet Well) have remained relatively stable (Table 5).

5.3 Contaminant Fate and Transport

The physical and chemical properties of PCE dictate how it will interact with the environment. Parameters important to fate and transport of PCE include specific gravity, Henry's Law Constant (K_H), vapor pressure, vapor density, water solubility (C_{wsat}), organic carbon partitioning coefficient (K_{oc}), octanol-water partitioning coefficient (K_{ow}), distribution coefficient (K_d), and viscosity. Henry's Law constant (K_H), water solubility, and the distribution coefficient (K_d) are of particular importance for evaluating an organic contaminant's partitioning into various environmental media (soil, water, air).

The K_d of a compound describes the tendency of the compound to either adsorb to natural organic matter present in the soil or to remain in the aqueous or the pure phase. The K_d is a function of the fraction of soil that consists of organic matter (fraction of organic carbon [f_{oc}]) and the extent to which a compound K_{oc}. Often, the K_{oc} is estimated from the K_{ow}, which is the ratio of the concentration of a chemical in n-octanol and water at equilibrium at a specified temperature. A compound with a high K_{oc} value will

tend to attach to the soil organic matter or remain in nonaqueous phases. The attachment kinetics described by the K_d value are at best an estimate of the short-term chemical partitioning between the aqueous phase and soils. Fluctuations in groundwater elevation, changes in the compound or the soil attachment site caused by weathering processes, or water chemistry changes can result in the compound becoming remobilized in the dissolved phase.

In practice, a simplified K_d can be estimated using the organic carbon content of the soil (f_{oc}) and the contaminant partitioning K_{oc}. Large values of f_{oc} and K_d indicate an affinity of the contaminant to partition onto soil; small values indicate an affinity of the contaminant to remain in the aqueous phase upon encountering organic solids.

The net effect of sorption is to retard the transport of contaminants relative to the groundwater. At Hill Air Force Base (AFB), Operable Unit 10, the transport velocities of TCE and PCE were calculated as 0.30 and 0.16 ft/d, respectively, for a relatively low organic carbon content environment (CH2M, 2009). The organic contents of the Hill AFB sediments are likely greater than the organic content of the sediments present at the Site; as such, it is expected that groundwater flow rate and PCE velocities may be greater in the basin-fill deposits of the Site.

Significant levels of daughter products of anaerobic PCE degradation, such as TCE, dichloroethene (DCE), and vinyl chloride have not been detected in deep groundwater collected from monitoring wells or water supply wells near the Site. This is likely because the aquifers are generally aerobic and oxidizing (i.e., unfavorable conditions for the anaerobic biological reductive dechlorination mechanism). However, TCE has been detected in two direct push groundwater samples (ESS-GW-04 and ESS-GW-07) in the East Side Springs area (UDEQ 2012), as well as in samples collected from temporary piezometers (EA 2016a) (Table 8). It is unknown if the TCE is an abiotic or biotic degradation product from natural attenuation of the 700 South 1600 East PCE plume, or if the TCE is from an entirely different source than the VA Medical Center. However, the mildly-reducing and anoxic groundwater conditions measured in the shallow East Side Springs groundwater is more favorable for the anaerobic reductive dechlorination of PCE.

PCE and daughter products have also been identified in soil-gas and indoor air samples collected in the East Side Springs area, indicating volatilization as a pathway for chlorinated ethene degradation from shallow groundwater.

6. Data Gaps

Data gaps for the conceptual site model are summarized in Table 9; this table defines the data gaps, presents what data are already known that may be used to address the data gap, details what data are required to address the data gap, informs how the data will be applied to filling the data gap, and suggests what investigative tools or methods may be useful in the process. The remainder of this section discusses these identified data gaps in more detail.

6.1 Identify the Source Area(s)

The sanitary sewer line associated with VA Medical Center, Building 7 (Figure 3) is the assumed source area for the PCE plume. However, few data are available tracing the PCE plume directly back to this location. If most of the contamination has already been "flushed out" of the vadose zone, linking the sewer line or Building 7 to existing PCE-impacted groundwater may not be possible. Never-the-less, a thorough investigation of this area is required. If the results of this investigation indicate that Building 7 and the sewer line are not the definitive source area, or not the only source area (e.g., PCE identified

upgradient of the VA Medical Center), then this phase of the investigation will continue to assess other potential source areas such as the former Army National Guard vehicle maintenance facility, or other potential areas north/northeast of the VA Medical Center. Methods to investigate the source areas are described below.

6.1.1 Soil-gas Sampling

Real-time soil-gas sampling will be used to identify locations where residual contamination is present in the soil. This assessment would be used as a cursory evaluation tool to better focus additional phases of the investigation, such as borehole drilling to collect soil samples and the installation of monitoring wells.

6.1.2 Field Sensing and Soil Sampling

If preliminary soil gas data indicates the potential presence of a source area, direct push drilling technology equipped with field sensing instruments (e.g., membrane interface probe) will be used to further assess the source area and collect confirmation soil samples. Soil samples will be needed to confirm contamination in the soil and whether soil contamination is present at concentrations that may still contribute to groundwater contamination and warrant remediation.

6.1.3 Monitoring Wells

Once a source area is identified, monitoring wells will be required to determine if contamination in the vadose zone is continuing to migrate to groundwater and evaluate the results of future source area mitigation and cleanup.

6.2 Characterize the Site Geology, Hydrostratigraphy, and Hydrogeology

To better understand likely groundwater flow and contaminant migration paths, it is important to better characterize the geology, hydrostratigraphy, and hydrogeology of the local basin-fill aquifer. Instrumentation, testing, and sampling of existing wells, as well as the installation of additional groundwater monitoring wells, will be fundamental to the characterization.

6.2.1 Geology

Conduct further detailed review of existing well and exploratory borehole logs (Table 10 and Attachment C) to better understand subsurface lithology, depth-to-bedrock, and potential marker beds that could be laterally continuous and compare to data obtained from new borings:

- Abandoned VA Medical Center Exploratory Borehole (Water Right No. 1057004M00); 1,004 ft total depth.
- University of Utah Exploratory Borehole (Water Rights No. 0757007M00 and 0657008M00); 1,508 ft total depth.
- Collect detailed lithology descriptions during installation of additional groundwater monitoring wells:
  - Determine the fraction of soil that consists of organic matter (f_{oc}) to determine a site-specific PCE K_d value.

- Develop more detailed cross-sections of the local subsurface stratigraphy; attempt stratigraphic correlations.

- Determine the thickness of the vadose zone in source areas; characterize the properties of the vadose zone to evaluate the migration of PCE from the source area to groundwater

6.2.2 Hydrostratigraphy and Hydrogeology

Determine hydrostratigraphic intervals:

- Validate the hydrostratigraphic zones assigned to existing well screen intervals (i.e., are the wells representative of upper versus lower potentiometric surfaces; are the wells representative of perched aquifers, or as suggested above, just shallow and deeper parts of the unconfined aquifer). Validation will be conducted through the comparison of data from new wells to be installed during site investigation, the long-term results from water level data collection, and aquifer testing

- Install multi-level monitoring wells constructed in a manner that permits characterization of groundwater flow conditions (e.g., horizontal and vertical hydraulic gradients and groundwater flow directions); aquifer testing (e.g., determine hydraulic gradients, hydraulic connectivity, and hydraulic conductivity and transmissivity); and long-term water level data collection (e.g., installation of pressure transducers).

- Install pressure transducers to monitor groundwater elevation changes during pumping of the U of U #1 pumping well:

  - Use data to understand how hydraulic gradients and groundwater flow directions are affected by pumping.

  - Use data to understand how pumping cycles may affect PCE transport.

- Characterize the geochemical conditions of the aquifer by collecting field parameter (temperature, pH, dissolved oxygen concentration, oxidation-reduction potential, specific conductivity), dissolved major cation and anion concentrations, TDS concentrations, and stable isotope (i.e., oxygen and hydrogen) data:

  - Use geochemical data, if possible, to develop signatures of specific hydrostratigraphic zones.

  - Use the data to determine groundwater flow paths, mixing relationships, and recharge areas.

  - Use the data for insight into what types of chemical contaminant degradation processes may be occurring in the environment.

6.3 Delineate Plume Boundaries and PCE Concentrations

The lateral boundaries of the 700 South 1600 East PCE plume are not well-defined. The vertical extent is also not well-defined. Additional data are required to delineate these boundaries and to contour PCE concentrations across the site. The 2016 shallow groundwater, surface water, soil and soil-gas investigation of the East Side Springs area (EA 2016a) better delineated the toe of the PCE plume, but

additional shallow groundwater data are required west and southwest of the East Side Springs area to delineate these boundaries. Further evaluation of the East Side Springs area is ongoing as part of the AOU-1 RI.

6.3.1 Direct Push

Direct push technology was utilized in 2016 for installation of temporary groundwater sampling points and long-term temporary piezometers in the East Side Springs area in support of the AOU-1 RI. While direct push proved useful in the shallower portions of the plume, there was difficulty advancing beyond approximately 40 ft bgs due to the presence of cobbles. Because of the limitations, the extent of PCE to the west and southwest of the East Side Springs area could not be confirmed. Additional groundwater sampling using a different technique is required along the western edge of the East Side Springs area, downgradient of the Wasatch Fault, as well as near the southwestern edge of the identified PCE groundwater plume. In these specific locations, the point at which PCE is no longer detected in shallow groundwater has not yet been determined.

6.3.2 Monitoring Wells

Multi-level groundwater monitoring wells will be installed to evaluate long-term PCE concentrations and determine hydrostratigraphic properties and hydrogeological parameters (see subsequent section). The well network will include:

- Wells in the core of the plume
- Wells along the plume boundaries
- Downgradient sentinel wells to monitor plume migration and expansion
- Upgradient wells to monitor background conditions
- Larger-diameter wells to facilitate aquifer testing
- Monitoring wells screened in specific hydrostratigraphic intervals

6.3.3 Spring, Seep, and Surface Water Samples

The shallow groundwater piezometers, springs and seeps in the East Side Springs area will continue to be sampled to determine the lateral and downgradient extent of PCE contamination. The location of the springs with relation to contaminant concentrations may be useful in evaluating potential groundwater flow paths. Additional shallow groundwater wells may be added southwest of the East Side Springs area to further assess the downgradient toe of the PCE plume.

6.4 Evaluate Natural Attenuation “Lines of Evidence” for PCE

The overall goal of performing PCE concentration, plume mass, and plume migration trend analyses is to evaluate if natural attenuation processes are acting on the PCE plume and if natural attenuation could be incorporated as a component of the remedy.

The EPA (1999) lays out a general three-tiered framework for the appropriate implementation of monitored natural attenuation. These three tiers of site-specific information, or “lines of evidence,” are:

1. Historical groundwater and/or soil chemistry data that demonstrate a clear and meaningful trend of decreasing contaminant mass and/or concentration over time at appropriate monitoring or sampling points.

2. Hydrogeological and geochemical data that can be used to demonstrate indirectly the type(s) of natural attenuation processes active at the Site, and the rate at which such processes will reduce contaminant concentrations to required levels.

3. Data from field or microcosm studies (conducted in or with actual contaminated site media) that directly demonstrate the occurrence of a particular natural attenuation process at the Site and its ability to degrade the contaminants of concern (typically used to demonstrate biological degradation processes only).

For the Site, collecting data to substantiate the Tier 1 and Tier 2 "lines of evidence" will be the focus early in the RI. To evaluate natural attenuation "lines of evidence," 5 years of consecutive groundwater monitoring data are generally required.

6.4.1 Tier 1

Tier 1 "Lines of Evidence" require statistical analyses of PCE plume stability and PCE concentrations trends at individual wells.

Plume Stability

Plume stability will be evaluated based on long-term monitoring well data and evaluated using a statistical trend analysis program. The primary metric for assessing overall plume stability are temporal trends in plume mass.

PCE Concentrations Trends at Individual Wells

The dissolved PCE concentration will be analyzed on a well-by-well basis over the same time period used for the plume mass analysis. Three different analyses can be used in the trend analysis:

1. Mann-Kendall trend analysis
2. Time series plots
3. Regression analysis following EPA (2011) guidance

The Mann-Kendall trend analysis determines if PCE concentration trends at an individual well are decreasing, increasing, or stable. These individual well analyses can be compared to the overall plume stability analysis. It should be noted that increasing trends at an individual well does not signify a concern from a plume stability and natural attenuation perspective, as some movement of mass within plumes is common even as the plume as a whole is attenuating.

Time series plots provide a visual confirmation of the plume-mass and well-trend analyses. In some cases, a Mann-Kendall analysis, using a historical data set, may indicate a decreasing or increasing trend for an individual well; but upon examination of the time-series plot, more recent data may suggest the opposite trend. In these cases, these wells warrant continued assessment including further statistical trend analysis when sufficient results are available.

Regression analysis at individual wells can provide rate constants for attenuation that provide a "clear and meaningful trend of decreasing contaminant concentration over time (EPA 2011)." Because higher-rate constants mean faster remediation timeframes, simple calculations in a spreadsheet can be used to determine whether the rate constants are different from zero at some predetermined level of statistical

confidence, and to extract the statistical confidence interval on the rate of attenuation (i.e., predict how long it will take for groundwater in the well to reach the maximum contaminant level).

6.4.2 Tier Two

Tier 2 evidence consists of hydrogeological and geochemical data that can be used to demonstrate indirectly the type(s) of natural attenuation processes active at the Site and the rate at which such processes will reduce contaminant concentrations to required levels.

In many cases involving chlorinated solvent plumes, Tier 2 evidence focuses on demonstrating highly anaerobic and strongly reducing conditions; geochemical conditions that are favorable for anaerobic reductive dechlorination by native microbial consortia. In the case of the Site, where literature data suggest that the subsurface environment is aerobic and oxidizing, and anaerobic biodegradation daughter products (i.e., TCE, vinyl chloride) are generally absent in groundwater, or in the case of TCE, occur very sparingly only at the downgradient margin of the plume and may be a primary contaminant from a different source, the Tier Two evidence will need to focus on other natural attenuation mechanisms such as advection and dispersion, adsorption, and abiotic degradation.

Advection and Dispersion

In order to evaluate advection and dispersion, site-specific hydraulic conductivities and gradients will need to be understood. These parameters can be determined through aquifer testing, potentiometric contouring, and soil and sediment characterization.

Adsorption

In order to evaluate adsorption, site-specific f_{oc} and K_d values will need to be determined. These parameters can be determined through soil and sediment collection at various depths within the contaminated aquifers.

Abiotic Degradation

If data from Tier 1 suggest that the PCE plume is naturally attenuating, then abiotic degradation mechanisms can be considered as a potential natural attenuation pathway. Evaluation of abiotic degradation mechanisms can include mineralogical analyses of soil and sediment and groundwater analysis for specific abiotic degradation byproducts.

6.5 Identify Potential Exposure Points

To understand human and ecological risks associated with the 700 South 1600 East PCE plume, it is first important to understand the pathways in which potential receptors may be exposed to contamination. The potential exposure pathways include groundwater (as drinking water and irrigation water), surface water (groundwater from springs and seeps that reaches the surface forming drainages that some residents have incorporated into landscaping features [e.g., ponds, creeks, canals]; or may enter the storm drain network), and soil-gas (off-gassing of shallow groundwater resulting in vapor intrusion into homes and businesses). To address potential exposure pathways, it is necessary to identify physical locations where potential receptors may contact exposure pathways.

6.5.1 Groundwater

Detections of PCE in municipal drinking water well SLC-18 were first identified in 1997, with a maximum concentration of 2.23 µg/L measured in October 2004. In 2016, the concentration of PCE was non-detect (Table 5); however, the well remains not operational. No other drinking water wells are located in the estimated footprint of the PCE plume; however, drinking water wells downgradient and cross-gradient of the Site should be evaluated during the RI.

Several irrigation wells are located within or in the vicinity of the estimated PCE plume footprint, including the U of U #1 pumping well and the Mt. Olivet irrigation well. Detections of PCE in the Mt. Olivet irrigation well have been present since 1990, with a maximum concentration of 184 µg/L measured in 1997. In 2016, the concentration of PCE was 40 µg/L (Table 5). PCE-impacted irrigation wells have the potential to spread PCE-impacted groundwater on the land surface, which may pose a risk to human and ecological receptors. As such, irrigation wells in the vicinity of the Site should be evaluated during the RI.

6.5.2 Springs and Seeps

PCE-impacted groundwater daylights in several springs and seeps in the East Side Springs area, leading to PCE-impacted surface water (e.g., drains, ponds, and sumps). PCE-impacted surface water may pose a risk to human and ecological receptors that come into contact or ingest the surface water. While identification of PCE-impacted springs, seeps and surface water in the East Side Springs area has been completed (EA 2016a), evaluation of the data and assessment of the risk is on-going as part of the AOU-1 Remedial Investigation.

6.5.3 Soil-Gas

Homes that overlie or are in direct contact with shallow groundwater within the footprint of the delineated PCE plume are at risk for vapor intrusion. In the East Side Springs area, soil-gas sampling was performed and indoor air sampling is on-going; evaluation of the data and assessment of the risk will be incorporated into the AOU-1 RI.

TABLE 9
Conceptual Site Model Data Gap Assessment
Conceptual Site Model Update 700 South 1600 East PCE Plume AOU-1: East Side Springs, Salt Lake City, Utah

Data Gap	Available Data		Data Required	Data Application	Investigation Methods
Identify the Source Areas	VA Medical Center Building 7	• Soil and soil-gas data • Sanitary sewer line video • Monitoring well network	Definitive evidence of a historical or continuing source of tetrachloroethene (PCE) contamination; this could be one or more identified "hot spot(s)"	• Delineate the source area • Determine source area PCE concentrations • Determine if source area is a continuing source for groundwater contamination • Determine whether other sources are contributing to the PCE plume by understanding distribution of PCE with respect to Building 7	• Soil-gas probes to screen locations • Soil samples • Groundwater data from source area monitoring wells
	Former Utah National Guard Vehicle Maintenance Facility	Soil-gas data	Definitive evidence of a historical or continuing source of PCE contamination; this could be one or more identified "hot spot(s)"		
	Former US Forest Service Helicopter Pad	None	Definitive evidence of a historical or continuing source of PCE contamination; this could be one or more identified "hot spot(s)"		
Site Geology	• Literature data from USGS, UGS, and other peer-reviewed publications • EPA well and boring Driller's Logs; VA Medical Center and University of Utah boring logs, available through UDWRi • Lithologic correlations from the USGS • USGS and UGS geologic and fault maps		• Detailed borehole lithology through PCE-impacted stratigraphy • Vadose zone thickness in the source area and footprint of the plume	• Correlate lithology in cross-sections to better understand potential aquifers, preferential flow paths (if any), and perching confining layers • Evaluate migration of PCE from the source area to groundwater	• Detailed borehole logging during drilling of monitoring wells
Site Hydrostratigraphy	• Literature data from USGS, UGS, and other peer-reviewed publications • Groundwater elevation data from existing monitoring wells and production wells		Aquifer testing data from the unconfined aquifers east of the East Bench segment of the Wasatch Fault; and the shallow unconfined and deeper confined aquifers west of the East Bench segment of the Wasatch Fault	Characterize and define the hydrostratigraphic units and aquifers based on potentiometric elevations and hydrogeological parameters	Multi-level monitoring wells, constructed in a manner that permit: • Aquifer testing • Groundwater sampling • Installation of pressure transducers
Site Hydrogeology	• USGS, UGS, and other peer-reviewed literature data about the regional shallow basin-fill aquifer • Previous groundwater models		Site-specific groundwater parameters, including: • Water level measurements • Vertical hydraulic gradients • Horizontal hydraulic gradients • Hydraulic connectivity/transmissivity • Groundwater flow rate • Groundwater geochemical parameters	• Apply the data to hydrostratigraphic interpretations • Use geochemical data as a signature of specific hydrostratigraphic zones • Use the data to determine potential groundwater flow paths, mixing relationships, and recharge • Use the data for insight into what kinds of chemical contaminant degradation processes may be occurring in the environment	• Collect temperature, pH, dissolved oxygen (DO) concentration, oxidation-reduction potential (ORP), specific conductivity, dissolved cation and anion concentrations, total-dissolved-solid concentrations, and stable isotope (i.e., oxygen and hydrogen) data from groundwater monitoring well network • Use groundwater data analysis tools (e.g., Piper plots and Stiff Diagrams) to understand relationships between hydrostratigraphic units and recharge sources
PCE Plume Boundaries and PCE Concentration Contours	• Existing monitoring well network that poorly delineates the shape, depth, and concentration of PCE-impacted deep groundwater • Shallow groundwater, spring, seep, surface water, soil, soil gas and indoor air data from the East Side Springs Area (toe of the plume)		• Multi-level groundwater data from the core, and periphery of PCE plume to define the vertical and lateral extent of PCE-impacted groundwater • Shallow groundwater data from the western and southwestern edge of the East Side Springs area	• Develop a PCE plume map and cross-sections with defined lateral and vertical PCE concentration contours • Use PCE plume map and cross-sections to evaluate potential receptors, assess PCE plume migration, and ultimately, evaluate plume remediation	• Develop a comprehensive monitoring well network to collect long-term groundwater data

TABLE 9
Conceptual Site Model Data Gap Assessment
Conceptual Site Model Update 700 South 1600 East PCE Plume AOU-1: East Side Springs, Salt Lake City, Utah

Data Gap	Available Data		Data Required	Data Application	Investigation Methods
PCE Concentration Trends and Plume Stability	Historical groundwater and spring water PCE data		Long-term (5-years) groundwater PCE concentration data from a comprehensive monitoring well network	• Plume stability is assessed using temporal trends in plume concentration and mass • Mann-Kendall trend analysis determines if PCE concentrations trends at an individual well are decreasing, increasing or stable • Time series plots are used to visualize data trends • Regression analysis at individual wells can provide rate constants for attenuation	• Mann-Kendall trend analysis performed using a statistical trend analysis program • Time series plots generated in graphical database (Excel) • Regression analysis calculations performed in a spreadsheet (Excel) to determine rate constants at a predetermined level of statistical confidence
Natural Attenuation Processes	Literature values for the shallow basin-fill aquifer indicate that the environment is likely oxic and not conducive to anaerobic biodegradation processes		• Site specific hydrogeologic data (see above) • Site-specific f_{oc} and K_d values • PCE daughter product concentrations in groundwater • Field parameters, such as DO, ORP, iron and sulfate concentrations	Generate hydrogeological and geochemical data that can be used to demonstrate indirectly the type(s) of natural attenuation processes active at the site, and the rate at which such processes will reduce contaminant concentrations to required levels (e.g., MCL)	Multi-level monitoring wells, constructed in a manner that permit: • Groundwater sampling for field parameters and VOC concentrations • Collection of soil samples below the water table to determine f_{oc} value and evaluate minerals present that may promote abiotic degradation processes (e.g., magnetite)
Exposure Pathways	Groundwater	PCE-impacted groundwater has been identified at the SLC-18 municipal drinking water well and the Mt. Olivet irrigation well	Map showing drinking water wells and irrigation wells that may be impacted by future migration of the PCE plume	Evaluate potential risk to the drinking water and irrigation wells given knowledge of plume stability, PCE transport rate, and groundwater flow direction	Compare mapped well locations to the PCE plume dynamics (developed to fill previous data gaps)
	Shallow groundwater, springs and seeps	Shallow groundwater, spring and seep, and surface water data from the 2016 investigation (EA 2016a)	Continued data collection	• Mann-Kendall trend analysis determines if PCE concentrations trends at an individual well are decreasing, increasing or stable • Time series plots are used to visualize data trends	• Mann-Kendall trend analysis performed using a statistical trend analysis program • Time series plots generated in graphical database (Excel)
	Soil-gas	Soil-gas and indoor air data from the 2016 investigation (EA 2016a)	Continued data collection	Determine location where mitigation is required	Indoor air verification sampling

TABLE 10
Additional East Bench Wells and Boreholes
Conceptual Site Model Update 700 South 1600 East PCE Plume AOU-1: East Side Springs, Salt Lake City, Utah

Well Name/Location Identification	Water Right Number	Latitude [1]	Longitude [1]	Elevation [1] (ft amsl)	Depth (ft bgs)	Comments
Bonneville Golf Course Well	57-4409	40.744161	-111.828967	4,695.00	240.00	USGS water level data available from 1934 to 2014
SLC-1064	57-4410	40.750550	-111.841161	4,659.00	502.00	Not measured/sampled by USGS since 1947
University of Utah Well - Diversion 1	57-112	40.763222	-111.836200	4,840.00	750.00	SLC-18 filed under same water right number
Abandoned VA Exploratory Borehole	1057004M00	40.756486	-111.837700	4,758.00	1,004.00	Stratigraphic log available
University of Utah Exploratory Borehole	0757007M00	40.768444	-111.840422	4,848.00	1,508.00	Stratigraphic log available
University of Utah Exploratory Borehole Well	0657008M00	40.768444	-111.840422	4,848.00	39.00	

NOTES:
ft amsl = feet above mean seal level
ft bgs = feet below ground surface

GW-06
PCE = 3.0 ug/L
TCE = 1.1 ug/L
DCE = 0.48J ug/L
Direct push groundwater sampling location with sample ID, PCE, TCE, and DCE concentrations

GW-16
PCE = 20 ug/L
TCE = 0.61 ug/L
DCE = 0.26J ug/L
Direct push groundwater sampling location converted to long-term temporary piezometer

Wasatch Fault line

Inferred PCE contour

PCE contour

Groundwater flow direction

Note(s) :
PCE, TCE, and DCE are displayed by each sample location under the location identifier.
When a PCE concentration is listed and TCE and/or DCE concentrations are not listed, TCE and/or DCE were not detected in the sample.
Samples were collected between 2/22/16 and 3/8/16
PCE contour labels are in ug/L

Source(s) :

GEOLOGIC LOG OF WATER-WELL CUTTINGS

UTAH GEOLOGICAL SURVEY

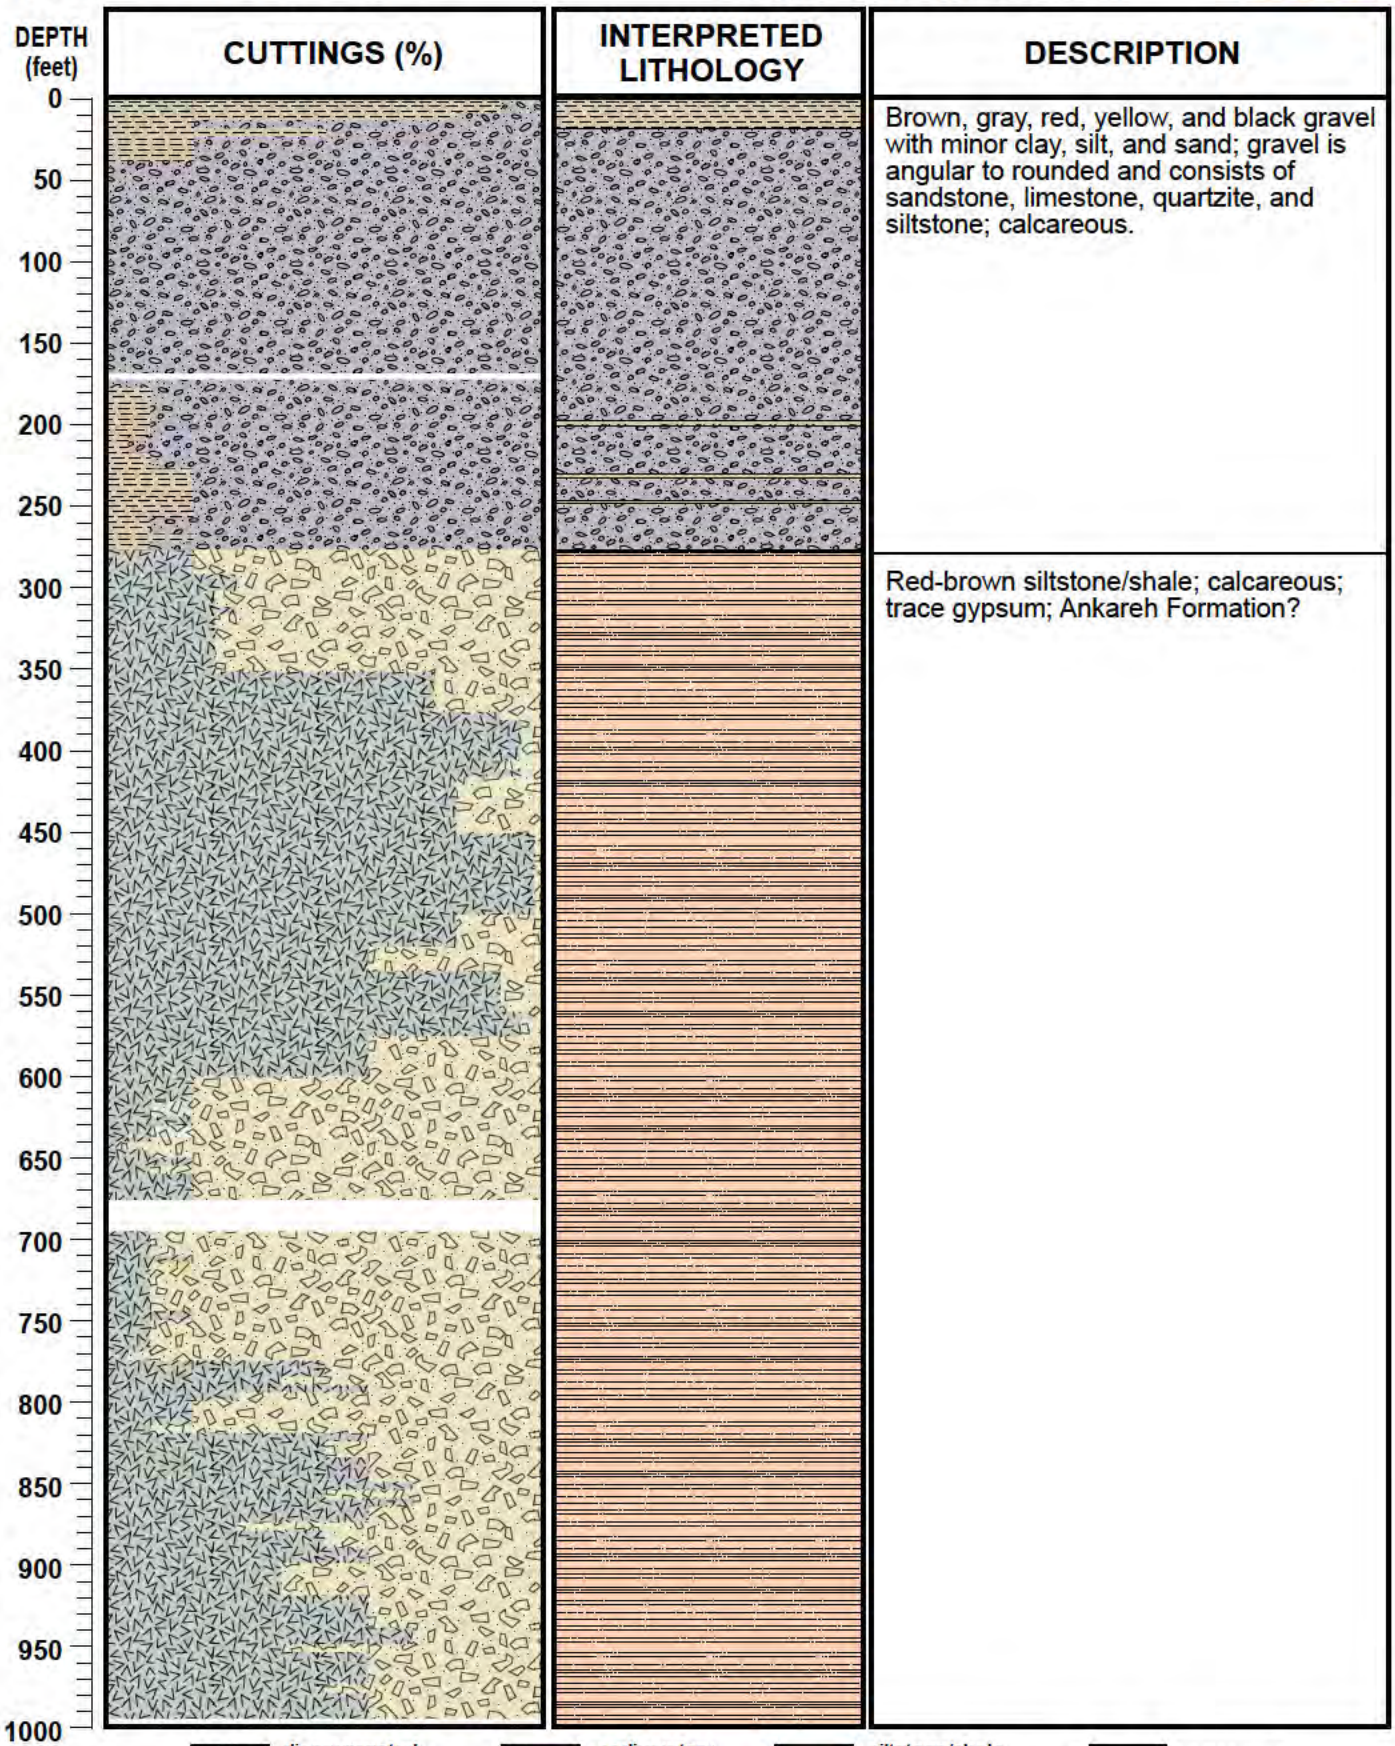
DWRi Appropriation #: 06-57-008-M00
Location: (D-1-1)4aba, Salt Lake County, Utah
Driller: Zimmerman Well Service
Well Owner: University of Utah
Win #: 427083
Geologist: Janae Wallace, 5/30/07



DESCRIPTION
Brown, gray, red, yellow, and black gravel with minor clay, silt, and sand; gravel is angular to rounded and consists of sandstone, limestone, quartzite, and siltstone; calcareous.
Red-brown siltstone/shale; calcareous; trace gypsum; Ankareh Formation?

disaggregated clay/silt and sand
sedimentary rock fragments
siltstone/shale
no sample
clay, silt, and sand
gravel

Attachment C-2.1

STATEMENT OF TECHNICAL REVIEW

AOU-1 Remedial Investigation for 700 South 1600 East PCE Plume, Salt Lake City, UT
Final 2017 Vapor Intrusion Investigation Field Data Report

The CH2M HILL, Inc. team has completed the technical review of the submittal of the Final 2017 Vapor Intrusion Investigation Field Data Report. Notice is hereby given that an independent technical review has been conducted that is appropriate to the level of risk and complexity inherent in the project, as defined in the Contractor Quality Control Plan. During the independent technical review, compliance with established policy principles and procedures was verified using justified and valid assumptions. This included review of assumptions; methods, procedures, and material used in analyses; the appropriateness of data used and level of data obtained; and reasonableness of the results, including whether the product meets the customer's needs consistent with the law and existing U.S. Army Corps of Engineers policy.

SECTION 1

Introduction and Background

This report presents analytical results from the 2017 vapor intrusion (VI) investigation for Accelerated Operable Unit 1 East Side Springs (AOU-1), which is part of the 700 South 1600 East Tetrachloroethene (PCE) Plume Superfund site in Salt Lake City, Utah. This report is being submitted on behalf of the U.S. Department of Veterans Affairs Salt Lake City Health Care System, which is working cooperatively with the U.S. Environmental Protection Agency (EPA) and the Utah Department of Environmental Quality to implement the remedial investigation (RI). The VI investigation results included in this report supplement the indoor air and soil gas sampling performed in 2015 and 2016. The 2015 and 2016 sampling was guided by the RI Work Plan (First Environment [FE], 2015) that included the sampling and analysis plan and quality assurance (QA) project plan attachments. The data collection activities briefly described in this report are based on those detailed in the *Minor Field Modification* (MFM) *#18* (Appendix A) (EA Engineering, Science, and Technology, Inc., PBC [EA], 2017) to the RI Work Plan (FE, 2015). Results of these data collection activities will help the Veterans Health Administration (VHA) refine the conceptual site model describing the nature, extent, fate, and transport of PCE associated with the PCE plume, specifically with respect to the potential for impacts to indoor air through the subsurface-to-indoor-air VI pathway.

AOU-1 is located in Salt Lake City, Salt Lake County, Utah, along the Wasatch Fault scarp within the general residential area bounded by 500 South and Michigan Avenue between 1100 East and 1300 East (Figure 1). In 2010, chlorinated volatile organic compounds (VOCs), including PCE and trichloroethene (TCE), were detected in the surface water associated with seeps and springs along the fault scarp. The location of the seeps and springs near residences and other occupied structures and the shallow depth to groundwater suggested the potential for VI into occupied structures. AOU-1 is defined as the area where springs are known to have PCE contamination and groundwater is within 50 feet of the ground surface. AOU-1 is surrounded by a 100-foot buffer zone.

SECTION 2

Summary of Previous Characterization Activities

VHA began collecting site-specific VI data within AOU-1 in January 2015 (FE, 2015). More than 1,000 soil gas and indoor air data points were collected from 35 structures consisting of private residences, schools, a church, and an elder-care facility. The structures represent a cross section of structure types, construction dates, depths to groundwater, and locations within AOU-1. Analytical results from those samples were used to update the conceptual site model for AOU-1, which in turn was used to identify data gaps and to prepare a sampling plan (EA, 2015) to fill those gaps.

The VI data collected in 2015 pointed to a portion of AOU-1 where a higher potential for VI to result in indoor air concentrations above risk-based screening levels (RBSLs) was noted. These data, combined with AOU-1 hydrogeological data, facilitated the delineation of a focus area for the 2016 VI sampling. In 2016, 10 residential and 1 public structure (East High School) within the 2016 focus area underwent individual VI investigation as outlined in the 2016 sampling plan (EA, 2015). The 2016 VI sampling activities and results are presented in the *2016 Vapor Intrusion Investigation Field Data Report* (EA, 2016).

The combined 2015 and 2016 VI sampling data were used to again update the AOU-1 conceptual site model, which facilitated the identification of a few remaining data gaps. The seven new residential structures sampled in 2017 were selected based on the 2015/2016 data to address the identified data gaps, as detailed in Section 3 of this report.

SECTION 3

Summary of 2017 Characterization Activities

This section presents a summary of, and rationale for, additional VI sampling activities conducted within AOU-1 from March 2017 to April 2017. Further detail regarding 2017 VI sampling methodology can be found in the MFM #18 (EA, 2017) to the RI Work Plan (FE, 2015). The 2017 VI program consisted of sampling 7 new structures (that is, not previously sampled as part of the 2015 and 2016 effort) and 11 previously sampled structures (previously sampled in 2015) in an area with higher potential for VI. The seven new structures (residential) were located in areas that had not previously been sampled and were selected to improve the spatial data distribution of AOU-1. The 11 previously sampled structures were re-sampled in 2017 to confirm the 2015 indoor air results, which are currently under third-party quality review due to uncertainty regarding correct sampling and field documentation procedures. Table 1 lists the number and type of samples collected at the 11 previously sampled structures and 7 new structures. Details for each of these objectives are provided in the following subsections.

3.1 2017 Sampling Focus Area

The VI data collected in 2015 and 2016 pointed to a portion of AOU-1 where a higher potential for VI to result in indoor air concentrations above RBSLs was noted. These data, combined with AOU-1 hydrogeological data, facilitated the identification of seven new structures to undergo full VI protocol sampling to improve the AOU-1 conceptual site model (Figure 2). In 2017, 7 new structures and 11 previously sampled structures underwent full and limited VI protocol sampling, respectively. See below for a definition of what constitutes a full and a limited protocol. The locations of these structures are shown on Figure 2. Collection of additional VI data from these residential structures within this focus area was conducted to support preparation of the RI report, including refining the conceptual model of VI within AOU-1 and evaluating potential risk.

3.2 Locations and Methods

The following three sampling goals outlined in the RI Work Plan were to be satisfied with the additional 2017 sampling:

- Sampling indoor air with EPA Method TO-15 analysis at 11 previously sampled structures to assess temporal variability in potential VI-related indoor air PCE concentrations and help address uncertainty related to 2015 TO-15 analytical results (Section 3.2.1).
- Sampling seven new (not previously sampled) structures within the focus area to assess spatial variability. This included screening indoor air and near-slab soil gas using a portable gas chromatograph/mass spectrometer called an INFICON HAPSITE® (HAPSITE). EPA Method TO-15 analysis of both indoor air and soil gas was also specified in the event an RBSL exceedance occurred during HAPSITE indoor air and soil gas screening.
- Analyze indoor air concentrations of PCE, TCE, cis-1,2-dichloroethene (DCE), vinyl chloride, and 1,4-dioxane by EPA Method TO-15 Selected Ion Monitoring (SIM) and other VOCs by EPA Method TO-15. Additionally, analyze indoor air PCE, TCE, and cis-1,2-DCE concentrations with a HAPSITE. The following subsections describe the locations and methods for each sampling goal.

3.2.1 Previously Sampled Structures

In 2015, VI data were collected from 36 structures within AOU-1 using the Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments (i.e., *Full VI Protocol,* Appendix H of the RI Work Plan [FE, 2015]). Eleven of these previously sampled structures were re-sampled in 2017 following the limited VI protocol sampling to confirm the 2015 indoor air results, which are currently under third-party quality review due to uncertainty regarding correct sampling and field documentation procedures.

Confirmation samples were collected per Attachment 1 of MFM #18 (EA, 2017), utilizing a limited VI protocol that includes HAPSITE screening of indoor air to identify potential interior background source(s) (no pressure cycling) and collection of up to 2, 24-hour SUMMA™ canister samples per structure of indoor air for EPA Method TO-15 and TO-15 SIM analysis. Soil gas and ambient air samples were not collected. Other components of the VI protocol (FE, 2015), such as detailed building surveys, were not repeated. Instead, an abbreviated interview and building survey were performed to identify any major changes that could have affected the 2017 sampling and data evaluation (recent remodels or household chemical storage, for example). Attachment 1 of MFM #18 (EA, 2017) presents a copy of the full VI protocol that conveys, in detail (via text highlights), those steps of the protocol that were retained in the limited VI protocol used for confirmation sampling. Table 1 lists the type of samples collected at these 11 structures and Figure 2 shows the locations of the SUMMA confirmation samples.

As noted, up to 2, 24-hour SUMMA canister samples were collected from each structure. The determination of where samples were collected and conditions under which an additional sample may be warranted is described in the *Limited VI Protocol* (Attachment 1 of MFM #18 [EA, 2017]).

3.2.2 New Structures

The goal of sampling structures not previously sampled during 2015 and 2016 was to gain a better understanding of the spatial extent of potential VI-related impacts associated with AOU-1 groundwater. Additional structures within the focus area are identified on Figure 2 and in Table 1. The 7 new structures underwent full VI protocol sampling (HAPSITE screening of indoor air to identify potential interior background sources, pressure cycling, and collection of up to 2, 24-hour SUMMA canister samples per structure, if an indoor air RBSL(s) exceedance was measured with the HAPSITE), as outlined in MFM #18 (EA, 2017). The VI protocol (FE, 2015) guided data collection at these structures. This included HAPSITE screening of indoor air and near-slab soil gas and EPA Method TO-15 analysis of both if screening levels were exceeded during HAPSITE screening of each.

SECTION 4

Results

Findings from the 2017 sampling event are summarized in the following subsections. This section is divided into subsections based on data collection activities outlined in Section 3 (previously sampled structures and new structures). Analytical results are compared to RBSLs and removal action levels (RALs) presented in Table 2.

4.1 Previously Sampled Structures (Limited VI Protocol)

Table 3 contains analytical results for the confirmation EPA Method TO-15 SIM samples collected at locations 0001-H, 0002-H, 0004-H, 0012-H, 0013-H, 0025-H, 0026-H, 0027-H, 0029-H, 0038-H, and 0064-H (Figure 2). These samples were 24-hour indoor air samples collected in 6-liter SUMMA canisters that had been individually laboratory-certified clean. Each sample was analyzed using EPA Method TO-15 and TO-15 SIM. Validated analytical results are provided in the *Quality Control Summary Report* (provided as Appendix B) and laboratory sample receipt notifications are provided as Appendix C. Indoor air in these previously sampled structures was screened with a HAPSITE to identify potential interior background source(s) (no pressure cycling) prior to 24-hour SUMMA canister sample collection. HAPSITE calibration reports associated with sampled locations are included in Appendix D and are organized by calibration date. The following subsections present the results of each limited VI protocol sampling event by structure.

4.1.1 0001-H

The limited VI protocol investigation at location 0001-H was conducted on March 15, 2017 and March 22, 2017. Two sample dates were required because the initial HAPSITE survey identified an interior background source containing PCE beneath the upstairs kitchen sink. The product was removed from the residence and a second appointment scheduled to collect a 24-hour SUMMA canister sample. A normal and field duplicate 24-hour SUMMA canister sample were collected at this residence. Table 3 and Table 4 present the EPA Method TO-15 and HAPSITE analytical results, respectively.

Vinyl chloride was the only target analyte that exceeded an indoor air RBSL but not the RAL at 0.17 and 0.19 micrograms per cubic meter ($\mu g/m^3$) in the normal and field duplicate samples, respectively (Table 3).

4.1.2 0002-H

The VI investigation at location 0002-H was conducted on March 22, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 5 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement living room. No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 5, respectively).

4.1.3 0004-H

The VI investigation at location 0004-H was conducted on March 13, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 6 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement (single large room). No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 6, respectively).

4.1.4 0012-H

The VI investigation at location 0012-H was conducted on March 13, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 7 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement living room. No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 7, respectively).

4.1.5 0013-H

The VI investigation at location 0013-H was conducted on March 9, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 8 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement living room. No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 8, respectively).

4.1.6 0025-H

The VI investigation at location 0025-H was conducted on March 13, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 9 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement living room. 1,4-Dioxane was detected at 2.3 $\mu g/m^3$, which exceeded the 1,4-Dioxane RBSL (0.56 $\mu g/m^3$) but not the RAL (Table 3). No other target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 9, respectively).

4.1.7 0026-H

The VI investigation at location 0026-H was conducted on March 9, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 10 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement living room. The initial 24-hour SUMMA canister indoor air sample was deployed on March 9, 2017. Upon retrieval of the initial canister on March 10, 2017 the final vacuum was positive; therefore, a new canister was deployed on March 15, 2017 and retrieved on March 16, 2017. The second canister was analyzed and the initial canister was not. No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 10, respectively).

4.1.8 0027-H

The VI investigation at location 0027-H was conducted on March 9, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 11 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement laundry room. A normal and a field duplicate 24-hour SUMMA canister sample were collected. No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 11, respectively).

4.1.9 0029-H

The VI investigation at location 0029-H was conducted on March 30, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 12 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement living room. No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 12, respectively).

4.1.10 0038-H

The VI investigation at location 0038-H was conducted on April 10, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Table 13 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the basement living room. A normal and field duplicate 24-hour SUMMA canister sample were collected. No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 13, respectively).

4.1.11 0064-H

The VI investigation at location 0064-H was conducted on April 13, 2017. This location was not previously sampled in 2015, but was sampled in 2017 following the resident's request. The residence underwent a limited VI protocol sampling event, per the request of VHA. No interior background sources were identified within the residence during the HAPSITE survey. Table 14 presents the HAPSITE survey analytical results for this structure.

The 24-hour SUMMA canister indoor air sample was collected in the ground-level living room (single-story residence). No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey or the 24-hour SUMMA canister sampling at this structure (Tables 3 and 14, respectively).

4.2 New Structures (Full VI Protocol)

The following subsections present the analytical results of the HAPSITE survey/pressure-cycling along with sample locations and sample condition descriptions for the seven new structures sampled in 2017 (0057-H, 0058-H, 0059-H, 0060-H, 0061-H, 0062-H, and 0063-H). HAPSITE calibration reports are included in Appendix D and are organized by calibration date. HAPSITE calibration parameters were within the specifications defined in the RI Work Plan (FE, 2015).

4.2.1 0057-H

The VI investigation at location 0057-H was conducted on April 5, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Three targeted differential pressures (-5, -10, and 5 pascals [Pa]) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 15 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey and pressure cycling event at this structure (Table 15). No indoor air samples were collected for EPA Method TO-15 analysis.

No target analytes were detected above the soil gas RBSL in the near-slab soil gas (Table 15).

4.2.2 0058-H

The VI investigation at location 0058-H was conducted on March 6, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 16 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey and pressure cycling event at this structure (Table 16). No indoor air samples were collected for EPA Method TO-15 analysis.

No target analytes were detected above the soil gas RBSL in the near-slab soil gas (Table 16).

4.2.3 0059-H

The VI investigation at location 0059-H was conducted on March 17, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 17 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

Vapors entering the residence basement laundry room floor drain during induced negative pressure exceeded both the PCE indoor air RBSL and RAL and the TCE indoor air RBSL. Vapor screening samples were collected with the HAPSITE probe 1 inch above the floor drain and not in the breathing zone. All screening samples collected within the breathing zone during the HAPSITE survey and pressure cycling were below the indoor air RBSLs (Table 17). For this reason, no indoor air samples were collected for EPA Method TO-15 analysis, in accordance with the approved VI sampling protocol.

No target analytes were detected above the soil gas RBSL in the near-slab soil gas (Table 17).

4.2.4 0060-H

The VI investigation at location 0060-H was conducted on March 7, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 18 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey and pressure cycling event at this structure (Table 18). No indoor air samples were collected for EPA Method TO-15 analysis.

No target analytes were detected above the soil gas RBSL in the near-slab soil gas (Table 18).

4.2.5 0061-H

The VI investigation at location 0061-H was conducted on March 8, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were

exchanged during each pressure step. Table 19 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey and pressure cycling event at this structure (Table 19). No indoor air samples were collected for EPA Method TO-15 analysis.

No target analytes were detected above the soil gas RBSL in the near-slab soil gas (Table 19).

4.2.6 0062-H

The VI investigation at location 0062-H was conducted on March 29, 2017. No interior background sources were identified within the residence during the HAPSITE survey. Three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 20 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey and pressure cycling event at this structure (Table 20). No indoor air samples were collected for EPA Method TO-15 analysis.

No target analytes were detected above the soil gas RBSL in the near-slab soil gas (Table 20).

4.2.7 0063-H

The VI investigation at location 0063-H was conducted on March 21, 2017. Three interior background sources containing PCE were identified within the residence during the HAPSITE survey. These three products were removed from residence prior to pressure cycling. One additional PCE-containing product was identified at the beginning of the 5 Pa pressure cycle and was removed from the residence. Three targeted differential pressures (-5, -10, and 5 Pa) were achieved during pressure cycling. Approximately 2.5 air volumes were exchanged during each pressure step. Table 21 presents the HAPSITE analytical results from the HAPSITE survey and the pressure cycling event at this structure.

No target analytes exceeded indoor air RBSLs or RALs within the breathing zone during the HAPSITE survey and pressure cycling event at this structure (Table 21). No indoor air samples were collected for EPA Method TO-15 analysis.

No target analytes were detected above the soil gas RBSL in the near-slab soil gas (Table 21).

4.2.8 Additional Information

All field notes were scribed in spiral-bound notebooks during the 2017 sampling events. These notebooks included a field logbook, HAPSITE field forms, SUMMA field forms, pressure cycling field forms, VI investigation QA assurance checklist forms, and daily report forms. A scanned copy of all field notes is included in Appendix E. Chain-of-custody forms and Analytical Request forms for the EPA Method TO-15 and TO-15 SIM samples collected during the 2017 sampling events also are included in Appendix E. All field documentation was scanned and sent to the VHA and U.S. Army Corps of Engineers (USACE) for quality control review on a weekly basis for the first three weeks of sampling. Appendix F contains the native HAPSITE data reports for each sampled location.

In an effort to ensure that field documentation was performed in accordance with the QAPP and Sampling and Analysis Plan (SAP), a pre-field kickoff meeting took place with the field staff to discuss field documentation and the requirements of the QAPP and SAP prior to any sampling. A daily QA checklist to monitor compliance with the QAPP was completed.

Furthermore, quality assurance protocols were implemented to ensure supplemental sampling data would achieve project data quality objectives. During the first week of VI sampling, the USACE provided oversight in the field and an in-person meeting with the contractor, regulators, and VHA was conducted to review field documentation for accuracy and completeness. Additionally, the VHA and USACE routinely spot-checked field documentation throughout the sampling event. This was accomplished by submitting electronic scanned copies of all completed field documentation to the VHA and USACE weekly for review. Any noncompliance issues were identified and adjustments by the field team were made to resolve them. All field documentation is presented in Appendix E.

4.3 Deviations from Remedial Investigation Work Plan

During the 2017 VI investigative work, there was no deviations from the RI Work Plan (SAP, Appendix B of the RI Work Plan [FE, 2015]) and MFM #18 (Appendix A) (EA, 2017).

[a] TO-15 and TO-15 SIM confirmation samples were only to be collected at full VI protocol structures (new structures) if a residential indoor air screening level and/or soil gas screening level was exceeded during full VI protocol sampling. No residential indoor air and soil gas screening levels were exceeded during full VI protocol investigations. TO-15 and TO-15 SIM indoor air confirmation samples were collected at all limited VI protocol structures (previously sampled structures).

Notes:
Table 3 contains the TO-15 SIM analytical results. See Appendix B for TO-15 analytical results.
Bolded values are detections.
Shaded values are screening level exceedances.

µg/m³ = micrograms per cubic meter
AOU-1 = Accelerated Operable Unit 1 East Side Springs
EPA = U.S. Environmental Protection Agency
FD = field duplicate
IASL = residential indoor air screening level
ID = identification
J = Estimated value. The result is estimated due to associated quality control problems.
N = normal sample
RAL = residential removal action level
Res. = residential
SIM = selected ion monitoring
U = Not detected. The analyte was analyzed for but not detected above the method detection limit.

4/3/2017	10:33	2	CV2-040317	Calibration check	140%[a]		134%[a]	132%[a]	Relative percent difference (acceptable range > 70% or < 130%)

[a] No action was taken due to these RPD exceedances since prior sample results were either nondetect or below RSLs. A high RPD indicates that sample results are biased higher than the actual concentration. That is, actual indoor air detections are biased higher than the actual indoor air concentrations. For example, the TCE RPD for CV2-040317 was 134% and the TCE CV result for was 6.7 ppbv for a known calibration gas of 5 ppbv.

SUBJECT: Minor Field Modification to the Remedial Investigation Work Plan AOU-1: East Side Springs 700 South 1600 East PCE Plume Salt Lake City, Utah (July 2015)

1. Introduction

This document provides a description of the minor field modification to the Remedial Investigation Work Plan (RIWP) AOU-1: East Side Springs 700 South 1600 East Tetrachloroethene (PCE) Plume Salt Lake City, Utah (First Environment, Inc. [FE] 2015a) to conduct additional vapor intrusion (VI) sampling at up to 13 previously sampled structures and at up to seven new (not previously sampled) structures as described below. Minor Field Modifications #1 - #17 were provided in separate documents and detail changes to the RIWP and the Sampling and Analysis Plan (SAP) (Appendix A of the RIWP). The following modification is detailed below:

- Minor Field Modification (MFM) #18 – Supplemental VI sampling will be conducted in accordance with the protocols described in the sections below. This field modification includes additional VI sampling at up to 13 structures previously sampled in 2015 and up to seven new (not previously sampled) structures in an attempt to fill potential data gaps from the 2015 and 2016 AOU-1 remedial investigation (RI) VI evaluation. The supplemental sampling is being performed in the event that some or all of the 2015 HAPSITE and TO-15 VI investigation data is determined to be unusable. Usability is being assessed through verification of field and laboratory data, which has identified field notation discrepancies in addition to non-compliance with the project plans. The determination of 2015 VI data usability and whether the data meets project objectives is still in process.

  The 13 structures to be resampled were selected from the 2015 indoor air sampling locations by evaluating the 2016 groundwater and surface water data and selecting the 2015 indoor air sampling locations where 1) groundwater is known to be impacted by PCE, 2) where estimated depth to groundwater was less than fifty feet below ground surface, and 3) where 2016 surface water data (EA 2017) indicates elevated PCE concentrations in the vicinity of PCE impacted groundwater area 4) and the western most edge of the investigation area in the direction of groundwater flow where there is currently no data. The southwest extent of the groundwater PCE plume was not defined during the RI due to limitations of the Geoprobe (which could not drill to

depths exceeding 40 ft bgs). Therefore, locations 0010-H and 0028-H, near the presumed southwest extent of the shallow PCE plume were also retained for confirmation sampling.

The seven new structures were selected by contacting property owners in, or near, the data gap areas from the 2015 and 2016 AOU-1 RI VI evaluation and/or by soliciting volunteers downgradient of the data gap areas. Initial RI data evaluation suggests PCE impact in shallow (i.e., less than 50 ft bgs) groundwater near and east of the intersection of 900 South and 1100 East, and west of 1300 East. There were multiple residences that fell within this area of the shallow PCE GW plume who did not volunteer to have sampling conducted. Some of these residences have since granted access and the structures have been included for VI evaluation The supplemental sampling will be performed in accordance with the work plan requirements and this MFM to ensure data of sufficient quantity and quality are obtained to achieve project data quality objectives.

- In the event that the 2015 data usability assessment determines that some or all of the 2015 data is not usable or does not meet project objectives, the confirmation sampling with the additional new sample locations is expected to be adequate to meet the data quality objectives as outlined in Table 3 of the QAPP (Summary of Data Quality Objective Process). Specifically, principal study questions 1 and 2 of the DQO process address the problem statement regarding indoor air as indicated below:
    - Question 1 - Does vapor intrusion present a complete pathway to structures overlying AOU-1 and is it significant?
    - Question 2 – What is the lateral extent of AOU-1 groundwater contamination that may result in a complete pathway and significant vapor intrusion exposures in overlying structures?

  Data inputs with regard to addressing the indoor air path for both of these questions include (amongst others): indoor air VOC concentrations (collected over temporal and spatial ranges); shallow soil gas VOC concentrations; and groundwater and surface water VOC concentrations from the areas where surface water and groundwater have PCE contamination and is within 50 ft of the ground surface (plus a buffer of 100 ft) (EA 2017). Groundwater and surface water data collected to date in support of the RI have suggested that the area of PCE contamination in springs and groundwater within 50 ft of ground surface is generally located east of McClelland Street, west of 1300 East, south of 700 South and north of Yale (see preliminary PCE in groundwater contours on Figure 1). While not all of the 36 structures from the 2015 sampling event are included for confirmation sampling (many of which are outside this area), each of the confirmation samples (as well as the new VI sampling locations) are within this area. SUMMA TO-15 SIM data is propose be collected from each of the confirmation sampling locations and from those new locations where HAPSITE® results indicate exceedance of screening criteria. The QAPP also indicates that making the indoor air sampling available to owners of any structure within and adjacent to AOU-1 who volunteer for sampling will meet the acceptance criteria for the acceptable number of data points. These proposed confirmation and new sampling locations target areas within the bounds of AOU-1, will result in collection of data necessary to meet the project objectives, fulfills the spirit of sampling the structure of any volunteer within the AOU-1 boundary, and therefore, are expected to meet the data and project objectives as outlined in the QAPP.

2. Minor Field Modification #18 – Proposed Sampling Plan

This section presents the rationale and details for additional AOU-1 VI sampling. Sampling at up to seven new structures (not previously sampled as part of the 2015 and 2016 RI sampling effort) and resampling at 13 previously sampled structures is proposed for the supplemental sampling program. The 2017 supplemental VI sampling will be conducted during the heating season and is currently scheduled to begin in early March 2017. Except where specifically noted within this MFM, the sampling will be performed in accordance with field, HAPSITE®, and laboratory methods and standard operating procedures (SOPs); indoor air and soil gas sampling protocols; quality control (QC) and quality assurance (QA) provisions; and data validation requirements presented in the following planning and procedural documents:

- RIWP (FE 2015a)
- Quality Assurance Project Plan (QAPP) Update Revision 1 (EA Engineering, Science, and Technology, Inc., PBC [EA] 2016a) and Revision 2 (Department of Veterans Affairs [VA] 2017)
- SAP (Attachment A of the RIWP, FE 2015a); and
- Minor Field Modifications
    - Minor Field Modification #1 to the RIWP - Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments (FE 2015b);
    - Minor Field Modifications #3, #4, and #5 to the RIWP - Change of Analytical Method for Analysis of 1,4-Dioxane; Updates to the Analytical Methods, Parameters, and Sample Media; and Update of Health and Safety Plan (EA 2016b);
    - Minor Field Modifications #7 and #8 to the SAP - Change of Analytical Method for Analysis of 1,4-Dioxane and Updates to the Analytical Methods, Parameters, and Sample Media (EA 2016c)

Table 1 presents the type of information included in each of these documents that is relevant to the supplemental investigation.

2.1 SUMMA Confirmation Sampling

In 2015, VI data was collected from 36 structures within AOU-1 using the Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments (i.e., "full VI protocol", Appendix H of the RIWP [FE 2015a]). During a third-party QA review of the 2015 VI field, electronic, and laboratory documentation, several discrepancies and instances of noncompliance with the QAPP were identified. These discrepancies and instances of noncompliance include: inconsistent or missing information regarding where HAPSITE® data were collected; chains of custody forms that were illegible due to improper error correction practices; omission of sample times and dates from chain of custody forms; inconsistent information recorded on electronic field forms and field logbooks; and sample receipts and analytical run logs that were absent from the laboratory data reports. Due to these discrepancies, noncompliance with the QAPP, and the ongoing evaluation of the validity of the 2015 VI data, thirteen of the previously evaluated structures will undergo confirmation sampling.

The confirmation samples will be collected per the planning documents listed above, but utilizing a "limited VI protocol" that includes HAPSITE® screening of indoor air to identify potential interior background sources (no pressure cycling) and collection of up to two 24-hour SUMMA canister samples per structure. Soil gas and ambient air samples will not be collected. Other components of the VI protocol (FE 2015a), such as detailed building surveys, will not repeated. Instead, an abbreviated interview and building survey will be performed to identify any major changes that could affect the

sampling and data evaluation (recent remodels or household chemical storage, for example). Attachment 1 presents a copy of the "full VI protocol" that conveys, in detail (via text highlights), those steps of the protocol that will be retained in "limited VI protocol" that will be utilized for confirmation sampling. Table 2 lists the number and type of samples to be collected at these thirteen structures and Figure 1 shows the locations of the SUMMA confirmation samples.

As noted, up to two 24-hour SUMMA canister samples will be collected from each structure. The determination of where samples will be collected and conditions under which an additional sample may be warranted is described in the "limited VI protocol" (Attachment 1).

2.2 New Locations for Full VI Protocol

Up to seven new (not previously sampled) structures will be sampled in order to supplement 2015 and 2016 VI data (Figure 1). The additional structures to be sampled within AOU-1 are identified as potential new sample locations on Figure 1 and in Table 2. The samples will be collected per the planning documents listed above utilizing a "full VI protocol" (i.e., Appendix H of the RIWP) that includes pressure cycling monitored with the HAPSITE®. Additionally, if an indoor air screening level is exceeded during the full VI protocol sampling, up to two 24-hour SUMMA confirmation samples will be collected at said structure. Ambient air monitoring and near-slab soil gas analysis will be performed if required per the VI protocol (FE 2015a). A full interview and building survey will be conducted at each location in advance of VI sampling.

3. Analytical

Samples will be collected in individually certified clean SUMMA canisters per QAPP Update Revisions 1 and 2. SUMMA canisters will be sent to ALS Environmental in Salt Lake City, Utah for analysis of target volatile organic compounds (VOCs) via TO-15 selective ion monitoring (SIM) (for preliminary contaminants of potential concern [PCOPC]) or TO-15 (for other target analytes) per Table 7 of the QAPP Update Revisions 1 and 2 (EA 2016a, VA 2017). PCE will be analyzed via TO-15 SIM for indoor air samples. QC samples will be collected as specified in QAPP Update Revisions 1 and 2 (EA 2016a, VA 2017). Analytical results will be reported to the lowest achievable method detection limits and reliable quantification levels. Once results are received from the laboratory, data will be validated in accordance with the QAPP Update Revisions 1 and 2 (EA 2016a, VA 2017).

4. Quality Assurance

Additional QA protocol will be implemented in order to ensure supplemental sampling data will achieve project data quality objectives. During the first week of VI sampling, the US Army Corps of Engineers will provide oversight in the field and an in-person meeting with the contractor, regulators, and VA will be conducted to review field documentation for accuracy and completeness. Additionally, the VA will routinely spot-check field documentation throughout the sampling event. If any noncompliance issues are identified, then field audits and meetings will continue weekly until which time the issues are resolved.

In an effort to ensure that field documentation is performed in accordance with the QAPP and SAP, a pre-field kick off meeting will take place with the field staff to discuss all field documentation and to discuss the requirements of the QAPP and SAP. A daily QA checklist (Attachment 2) to monitor compliance with the QAPP will be completed. Once field work has commenced, the Project Manager will be responsible for ensuring field documentation is performed in accordance with the QAPP and SAP.

The field documentation for confirmation samples collected via Limited VI Protocol will consist of:

1. **Field Logbook**: The field logbook will contain all of the field notes specific to each residential limited VI protocol sampling event (i.e., HAPSITE® calibration information, time of arrival/departure, brief floor plan sketch with sampled locations, whether or not an interior source(s) was identified with the HAPSITE®, product manufacture name and its location, SUMMA deployment time, location, initial/final vacuum, canister/flow controller ID, Sample ID, etc.). This will be a Rite in the Rain® notebook with numbered pages.

2. **HAPSITE® Field Form**: HAPSITE® field forms will be used to log each HAPSITE® sample (run number, time, date, location, location description, sample ID, and detected VOC concentrations). One form will be dedicated to each sampled residence. HAPSITE® field forms will be spiral bound in booklet form.

3. **SUMMA Field Form**: SUMMA field forms will be used to log each SUMMA canister deployment. These forms will include the following information: sample location, sample ID, canister/flow controller ID, start/end time, start/end date, initial/final vacuums, flow controller flow rate, etc.). One form will be used per sample location. SUMMA field forms will be spiral bound in booklet form.

The field documentation for new samples collected via the Full VI Protocol Sampling will consist of the same documentation for the Limited VI Protocol with the addition of a pressure cycling field form where blower flowrates and differential pressures will be logged. The SUMMA field form will only be necessary if a screening level is exceeded during the Full Protocol VI sampling, and soil gas samples will be logged on the HAPSITE® field form.

5. Documentation and Reporting

The findings from the 2017 sampling will be summarized in a VI Field Report. Information that may result in the need for actions prior to the VI Field Report will be conveyed to the agencies during the regularly scheduled project-team conference calls.

Key Information and Associated Document
Minor Field Modification #18 to the Remedial Investigation Work Plan
AOU-1: East Side Springs, 700 South 1600 East PCE Plume, Salt Lake City, Utah

Document	Key Information
RIWP	• Project objectives, technical approach, and sample rationale • Appendix E - Risk Assessment Work Plan for identification of PCOPCs • Appendix H - Protocol for Performing Indoor Air and Near-Slab Soil Gas Assessments • Appendix I - Project Communications Plan for Contractor Field Staff
QAPP Update Revision 1 and 2	• Data quality, precision, and accuracy objectives • Required training and documentation • Target analyte list, laboratory analytical methods, quantitation limits, and SOPs • Instrument maintenance and calibration • Required quality control samples • Corrective action requirements • Data validation requirements
SAP (Appendix A of the RIWP)	• Sampling methodology and procedures, sample handling, sample designations, and sample documentation • Sample custody requirements • Field SOPs • VI field screening instrument instructions and HAPSITE® Operators Manual
Minor Field Modification #1	• Changes in the order of various components of the indoor air screening process (“full VI protocol”)
Minor Field Modifications #3 and #7	• Indicates analysis of PCOPCs, including 1,4-dioxane, to be completed by TO-15 SIM. TO-13 analysis is no longer required. • This field modification is a change to sections 6.2.1.3 and 6.2.2.2 of the RIWP and 4.1 and 4.2 of the SAP.
Minor Field Modifications #4 and #8	• Replaces Section 6.2.1 Indoor Air Quality Assessment of the RIWP and Section 4.1 Indoor Air Quality Screening, Characterization, and Verification of the SAP with QAPP Update Revision 1 and 2 Section 2.3.1. • Replaces Section 6.2.2 of the RIWP and Section 4.2 of the SAP (i.e., Near-Slab Soil Gas Investigation) with QAPP Update Revision 1 and 2 Section 2.3.2. • Replaces Section 6.2.3 of the RIWP and Section 4.3 of the SAP (i.e., Open-Field Soil Gas Investigation) with QAPP Update Revision 1 and 2 Section 2.3.3.
Minor Field Modification #5	• Replacement of the Health and Safety Plan (Appendix C of the RIWP) to reflect the health and safety protocols specific to EA Engineering, Science, and Technology, Inc. • Assesses the risks associated with potential and actual health and safety hazards and identifies those controls to be implemented during investigation activities.

PREFACE

Limited Protocol for Performing Indoor Air Assessments ("Limited VI Protocol")

The attached document, *Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments* (i.e., referred to as the "full vapor intrusion (VI) protocol" herein, and dated 17 July 2015), was included as Appendix H of the Accelerated Operable Unit 1 (AOU-1) Remedial Investigation Work Plan (RIWP). This document has been included in its entirety (below) to illustrate those steps from the "full VI protocol" that will be performed as part of the "limited VI protocol" noted in Minor Field Modification (MFM) #18. Steps that are highlighted in yellow in the "full VI protocol" constitute those items that are retained as part of the "limited VI protocol".

In addition, MFM #1, #2, #3, #4 and #8 represent approved changes to the "full VI protocol" and shall be reviewed prior to implementing the protocol. For example, since approval in July 2015, the following changes have been made to the "full VI protocol":

- The order of HAPSITE® operations to screen structures for indoor background sources was updated to begin with the use of analyze mode to identify indoor spaces with elevated concentrations of volatile organic compounds (VOCs). Followed by the use of survey mode to positively identify suspect indoor background sources of VOCs. (MFM #1, #4, and #8 [Attachments 1A – 1C, respectively]).

- Vinyl chloride is no longer a reported HAPSITE® analyte based on 2015 TO-15 sample results (MFM #4 and #8 [Attachments 1B and 1C, respectively]).

- Soil gas samples for TO-15 analysis will only be collected if measured PCE soil gas concentrations exceed the 370 micrograms per cubic meter ($\mu g/m^3$) (55.4 parts per billion by volume [ppbv]) screening level (SL) (QAPP Revision 2 [Department of Veterans Affairs (VA) 2017]).

- No soil gas samples will be analyzed using method TO-13 per the approved MFM #3 (Attachment 1B).

Where clarifications to the protocol based on previously approved minor field modifications are included in the text of the protocol, the clarifications are identified by bracketed red, italicized text so that the reader understands these are approved changes from the original approved protocol (standard black font).

FINAL

Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments
700 South 1600 East PCE Plume Superfund Site
Salt Lake City, Utah

PREPARED FOR: D. Lynne Welsh/VA Salt Lake City Health Care System

PREPARED BY: Scott Beckman and Ed Reid, First Environment, Inc.

COPIES: David Waite, CH2M-Hill; Rolf Lange, Avalon; Devin DeMarco, First Environment, Inc.

DATE: July 17, 2015

1.0 Introduction

This document provides a protocol for the use of real-time on-site gas chromatography/mass spectrometry (GC/MS) analysis to screen for indoor sources, identify potential points for vapor intrusion, screen for the presence of volatile organic compounds in soil gas and indoor air, and direct 24-hour SUMMA canister sampling at selected locations (with TO-15 analyses) to evaluate the potential for vapor intrusion in structures associated with the Accelerated Operable Unit-1 (AOU-1) portion of the 700 South 1600 East PCE Plume (Plume).

The AOU-1 Remedial Investigation will involve an assessment structure including residential, commercial, and public buildings within the Study Area. The objectives of the investigation are several-fold:

- Determine, using real-time indoor air sampling via portable laboratory equipment and confirmatory EPA TO-15 analyses for volatile organic compounds (VOCs), if there is an immediate threat to human health in structures associated with the Plume.
- Expedite the indoor air assessment using real-time data from a field-portable GC/MS to identify indoor sources and identify potential vapor intrusion points during negative depressurization followed by positive pressurization of the entire structure or key discrete portions, as determined practical in the field.
- Collect indoor and near-slab soil vapor data as part of a collaborative data-set that will support the overall remedial investigation of both the groundwater plume and vapor intrusion potential, development of a periodic indoor air monitoring program for AOU-1, future risk assessment, and refinement of the conceptual site model.
- Determine the relationship between a subset of co-located TO-15 grab samples and field-portable GC/MS air sample results for determining the comparability of the field instrument to provide acceptable and usable real-time data.

This vapor intrusion investigational approach was adopted from an Environmental Security Technology Certification Program (ESTCP) Project No. ER- 201119-Final Report (GSI, 2013) and ER-201119-GD- Standard Protocol (GSI, 2014) and provides an alternative to the conventional investigation method of indoor air and sub-slab testing. The project-specific Quality Assurance Project Plan (QAPP) and Sampling and Analysis Plan (SAP) (including

Standard Operating Procedures (SOPs) for HAPSITE preparation and general operation) were also used as references for this Protocol, as well as the Infinicon HAPSITE Smart Plus™ and HAPSITE-ER™ Operating Manuals.

The Protocol relies on the use of on-site data acquisition of indoor air volatile organic contaminants and near-slab soil gas using field portable gas chromatography/mass spectrometry (GC/MS) for real-time assessment of structures. The protocol also provides a methodology for locating and quantifying sources of indoor air contamination should indoor air contaminants be identified during the assessment process. For this study, the field portable instrument will be the HAPSITE Smart Plus™ or HAPSITE ER Chemical Identification System™ (HAPSITE). Indoor air constituents detected above initial action screening levels proposed by the Department of Veterans Affairs (VA) will be confirmed by conventional 24-hour SUMMA canister sampling. The SUMMA canister samples will be analyzed using Environmental Protection Agency (EPA) Method TO-15 Select Ion Monitoring (SIM) and TO-15 laboratory analyses by a National Environmental Laboratory Accreditation Program (NELAP)-certified off-site laboratory.

The following activities will be performed as part of the protocol. Real-time assessment using the HAPSITE™ will determine the nature and applicability of specific activities. For AOU-1, the decision criteria are contained in the technical memorandum: Vapor Intrusion Screening Levels and Removal Action Levels 700 South 1600 East PCE Plume, Salt Lake City, Utah dated 10/17/2014.

- Selection of Structures for Vapor Intrusion Assessment (Section 3.0) – selection of structures to be included in the Remedial Investigation.
- Pre-Assessment Activities (Section 4.0) – confirmation of access agreements/ permissions, schedules, and address for testing; property owner/occupant review of questionnaire for locating potential indoor air background sources; and building condition assessment for sampling locations.
- HAPSITE™ Use, Calibration and QC Checks (Section 5.0) – use and operation, initial calibration; continuing calibration and tuning checks, overnight storage, and regular maintenance.
- Outdoor (upwind) Real-time Qualitative Sampling (Section 6.0) - conduct ambient outdoor (background) testing at an upwind location adjacent to the structure using the HAPSITE ™ in analyze mode to identify presence of target VOCs.
- Initial (upon entry) Survey of indoor VOC Concentrations/Identification of Interior Background Sources (Section 7.0) – room-by-room (or groups of room openly connected) walk through of the structure using the HAPSITE™ in survey mode to identify the presence of any elevated VOC concentrations, followed by localized (sub-areas of rooms) assessments as indicated by initial results to identify and record locations of interior background sources.
- Survey of Potential Vapor Intrusion Entry Points (Section 8.0) – areas identified during initial building condition assessment inspection to assess for vapor entry points using HAPSITE™ in survey mode.
- Initial Real-Time Quantitative Sampling (Section 9.0) – under ambient conditions, interior floor-by-floor and (if necessary) room-by-room quantitative assessment of target chlorinated VOCs: Tetrachloroethylene (PCE); Trichloroethylene (TCE); cis-1,2-Dichloroethylene **(**cis-1-2-DCE); and, Vinyl Chloride (VC). *[Note that VC has been*

removed from the HAPSITE® analyte list per approved MFM #4 and #8 (Attachments 1B and 1C, respectively).]

- Negative Pressure Real-Time Quantitative Sampling (Section 10.0) – place the building interior, or if the structure is divided into discrete areas, the portion of the building interior identified as having the greatest potential for vapor intrusion, under negative pressure, and conduct continuous (repeated samples at a central location) quantitative sampling for target chlorinated VOCs during initial depressurization and air exchange, followed by quantitative sampling using the HAPSITE™ on all other floors while building is under negative pressure.
- Positive Pressure Real Time Quantitative Sampling (Section 11.0) – place the building interior, or if the structure is divided into discrete areas, the same portion of the interior where depressurization was previously performed, under positive pressure and conduct continuous (repeated samples at a central location) quantitative sampling in the same locations and sampling procedures as used during the negative depressurization.
- SUMMA Canister Sampling (Section 12.0) – SUMMA™ canisters (24-hour samples) deployed after interior background source are identified and after quantitative HAPSITE™ sampling under ambient and negative pressure, if data indicates exceedances of the established risk action screening levels for any analyte.
- Near-Slab Real-Time Soil Gas Sampling (Section 13.0) – perform real-time, near-slab soil gas quantitative evaluation of contaminants of interest using the HAPSITE™ in analytical mode. Collect SUMMA canister samples at selected sampling probe locations adjacent to structures where indoor SUMMA™ canisters were collected, plus at least two soil gas locations without detectable COCs in soil gas.
- Data Management and Distribution (Section 14.0) – data management and distribution to project participants.

2.0 Problem Definition

A PCE plume (Plume) has been detected in the vicinity of the George E. Wahlen VA Medical Center (VAMC or Facility). The Plume underlies the neighborhoods surrounding the intersection of 700 South and 1600 East in Salt Lake City, Utah, a blended commercial and residential area of approximately 300 acres. PCE was detected at parts per billion (ppb) levels in one of Salt Lake City's secondary drinking water wells (removed from service in 2004) and the Mt. Olivet Cemetery irrigation well. PCE has also been detected at ppb levels in shallow and deep groundwater, surface water springs, and in storm sewers in this area.

VA subsequently designated the primarily residential area on and just below the Wasatch Fault Scarp as AOU-1, also known as the East Side Springs area. This area is characterized by numerous small seeps and springs, some of which discharge PCE-containing groundwater to the land surface near the suspected downgradient margin of the PCE plume. The residential areas just to the north of AOU-1 and a dry gulch just to the east of AOU-1 are included in AOU-1. The northernmost and easternmost portions of AOU-1 are not currently known to contain springs or seeps, and the depth-to-groundwater beneath the surface is not known. However, the proximity of these areas to the groundwater table and springs containing PCE warrant further study to determine whether any subsurface contaminants related to the Site extend to those areas and pose risks to human health and/or the environment.

The primary public health concern within AOU-1 is the potential for vapor intrusion of chlorinated volatile organic compounds, associated with the Plume, into surrounding homes, schools, and other structures in the East Side Springs area. The potential public health threat is the accumulation of volatilized PCE and its degradation by-products from contaminated groundwater into proximal occupied structures above regional screening levels; thus creating an inhalation exposure hazard. The potential pathways for PCE (and associated degradation products) into indoor air may include the surrounding or underlying soil gas, surface water springs, and shallow groundwater in the vicinity of the structure or dwelling.

This protocol outlines performing real-time and conventional indoor-air assessment of structures associated with the East Side Springs in order to rapidly assess excess risk associated with contaminated indoor air resultant of VI and to obtain legally defensible data for future mitigation decisions.

3.0 Selection of Structures for Remedial Investigation Initial VI Assessment

Prior to field-activities, the VA and technical team will coordinate the solicitation of property owners for voluntary testing of their property for VI assessment. VA plans to approach the 50 or so property owners that have already indicated a willingness to allow testing and pending access permission, structures on these properties will constitute the initial group of buildings to be tested for potential vapor intrusion. VA's goal is to identify a sufficient number of structures within the known location of the Plume and outside the Plume that may exhibit a full-spectrum of indoor air vapor concentrations for the contaminants of interest. Of the 50 or so properties to date where owners have volunteered for testing, some are located within the approximate known areas of the Plume where PCE detections in the surface springs were encountered, some are above the Plume in areas where groundwater is at least 30 to 50 feet below the surface, some are located over shallow groundwater that is outside the Plume, and some are located a considerable distance from the known Plume extent and well above the groundwater table.

The rationale for testing a range of locations within the Remedial Investigation Area is to: (1) maximize the probability of encountering structures with a spectrum of measurable concentrations of the contaminants of interest in the known impact areas; and (2) maximize the probability of encountering some structures with no or minimal levels of the contaminants. The combined data-set will be used as an early guide to recruit additional sampling locations and prioritize the recruitment based on potential for vapor intrusion.

4.0 Pre-Assessment Activities

Pre-assessment activities include the following: (1) confirming that an access agreement/permission of the property owner is in place, confirming the schedule for the investigation, and the structure's address; (2) reviewing questionnaire responses in order to evaluate potential indoor air background sources; (3) identifying indoor air sampling locations and evaluating the structural conditions that may affect vapor intrusion; and (4) noting the locations of background sources (to the extent possible) of materials containing chlorinated volatile organics. The activities noted for 1, 2, and 3, above, may be done in advance of the arrival of the sampling team whenever possible. Removal of significant background sources, including non-target sources such as gasoline or paint thinners that are likely to potentially overwhelm the field instruments, will be discussed with owner upon arrival and removed from

the structure with their permission to the extent possible. For this effort, the assessment team will consist of two individuals, at least one of which is trained and certified by the equipment vendor on the use of the HAPSITE.

4.1 Confirmation of Access Agreements, Schedules, and Addresses

Prior to arriving at the testing site, the assessment team will confirm with the VA that permission for access is in place, the scheduled date and address are correct, and a responsible party will be at the building to grant access and provide pertinent information. For the day of the assessment, upon arrival of the sampling team, the property owner will be asked to close all windows, exterior and interior doors, and shut off any forced air climate control equipment for the duration of each sampling task that requires no air circulation (i.e., indoor source survey and entry point survey, negative depressurization). Between sampling tasks and during personnel breaks or lunchtimes, forced air climate controls can be restarted to maintain indoor temperatures. Homes with baseboard electric heat or hot-water radiator heat do not require systems to be turned off.

4.2 Review of Building Questionnaire Responses

A questionnaire will be filled out by the property owner or building occupant prior to on-site assessment and reviewed by the assessment team. The questionnaire will include information regarding the layout of the structure (e.g., number of floors, approximate square-footage, rooms on each floor, attached structures); and the type and location of potential background sources (dry cleaning, glues, solvents, fuels, cleaning products). This information will be used to (1) identify initial sampling locations; and (2) locate and document any potential background sources prior to conducting any screening or sample collection.

4.3 Building Survey

Upon arrival at the building, if the structure was not able to be inspected and the layout obtained prior to the sampling date, the assessment team will perform a walk-through to confirm the layout of the structure. The assessment team will sketch a floor plan layout showing each room on each level with approximate dimensions of each room. Any obvious interior background sources identified from the questionnaire or during the walk-through will be documented as to the type of product and its location within the structure. Unless the source is creating high concentrations of indoor VOCs that will overwhelm the HAPSITE™, all identified background sources will be left in place. The potential source and location will be recorded on the sampling record, as well as the presence of any fixed sources that cannot be removed such as new carpet, freshly painted surfaces, etc. From the building survey, initial quantitative sampling locations will be marked on the layout sketch. These initial locations shall be, at a minimum, on every level and generally centered within the level.

5.0 HAPSITE™ Use, Calibration, and QC Checks

5.1 HAPSITE™ Use

The HAPSITE™ will be operated by a KD Analytical Trained and Certified assessment team member. The trained assessment team member will be familiar with the general use of the instrument, as well as with the project specific measurements and QC requirements.

The HAPSITE™ will be used in two modes - Quantitative Analyze and Qualitative Survey. In Quantitative Analyze mode the instrument will detect and quantify the target chlorinated VOCs: PCE, TCE, cis-1,2-DCE, and VC. The sensitivity of the HAPSITE™ for chlorinated VOCs in

Analyze Mode is 0.1 to 0.5 µg/m3, which is below the characterization criteria (EPA RSLs; in parentheses) for PCE, but close to the criteria for the other selected target analytes: PCE (11.0 µg/m3, TCE (0.48 µg/m3), VC (0.17 µg/m3), and cis-1,2-DCE (no value established by EPA). In Qualitative Survey Mode the instrument will be used as a screening tool for the continuous-reading of the target analytes. The sensitivity of the HAPSITE ™ for the target analytes in Survey Mode is in the low mg/m3 range. Survey mode will be used to assess the location of background sources from indoor products and materials, as well as determine potential entry points for subsurface vapor contaminants.

For the Analyze Mode, a project-specific sample intake and analysis method has been developed for the HAPSITE™ by the operator focusing on the target analytes: PCE, TCE, cis 1,2-DCE, and VC. The selective ion monitoring (SIM) mode will be used to increase the detector sensitivity for the target analytes. The customized method for the HAPSITE™ will include selecting the characteristic ions for each compound targeted, the temperature settings, GC temperature profiles, including ramp times and rates, and the timing and mass measurements associated with each scan set in the method. The equipment vendor is providing the method programming pre-installed as a selection option on the HAPSITE™. These parameters can also be modified or reset according to manufacturer instructions provided in the HAPSITE™ Operations Manual (included as an attachment to the SAP). The method will be designed for low concentration samples (i.e., 0.1 – 10 ppbV range). However, if high concentrations are encountered (e.g., 100 – 1,000 ppbv), the method can be modified simply by reducing the sampling duration – effectively diluting the sample and raising the lower quantification limit for any lower concentration VOCs.

In the Survey Mode, the HAPSITE™ by-passes the GC column and sends a continuous sample directly to the mass spectrometer detector. Survey mode for this project will be used to continuously search for indoor background generating materials and for screening potential entry points for subsurface vapors. For the Survey Mode, the HAPSITE™ is carried from room to room and the concentrator probe placed near a suspected source or near potential vapor intrusion points (e.g., foundation cracks) to identify concentrations of VOCs, as further discussed below. *[Note that the order of HAPSITE® operations were updated in MFM #4 and #8 (Attachment 1B and 1C, respectively). The indoor air will be analyzed for VOCs using the field portable GC/MS in quantitation mode. Screening will be conducted on each level (basements and living/working floors). If VOCs are detected, the portable GC/MS will be run in survey mode to aid identification of background sources of VOCs such as chemical products and dry-cleaned clothing. If such sources are found, the resident will be asked to relocate the materials from the occupied structure to prepare for real-time air assessment (MFM #4 and #8 (Attachments 1B and 1C, respectively)).]*

5.2 Calibration and QC Checks

For the Analyze Mode, tuning, initial calibration, continuing calibrations, and QC checks will be performed to assure that the instrument meets the data quality objectives specified in the Quality Assurance Project Plan.

Prior to the analyses of any samples, blanks, or calibration standards in Analyze Mode, the instrument performance check (tuning check) will be performed to establish that the HAPSITE™ meets the mass spectral ion abundance criteria. The instrument tuning check (also known as the continuing calibration verification; CCV) gas will be analyzed initially following the calibration of the HAPSITE™ and once per 24-hour time period of operation. In the event the instrument performance check standard does not meet criteria, the HAPSITE™ will not be used in Analyze mode until corrections (including recalibration) are made in

accordance with the Operators Manual, however, the Survey Mode may be used to look for the selected ions of the chemicals of interest.

The HAPSITE™ will be calibrated using a minimum of five chemical concentrations that span the monitoring range of interest (0.1 ppbv to 100 ppmv) in an initial calibration sequence to determine instrument sensitivity and the linearity of GC/MS response for the target compounds (PCE, TCE, cis-1,2-DCE, and VC). QA criteria for calibration curve acceptability are: Relative Standard Deviation (RSD) <20%; RSD of RF < 30%; and curve fit R-Squared (R^2) ≥ 0.98, where the RSD % is the measure of the linearity of the concentration levels (ion counts) in the calibration curve for each compound; and the Relative Standard Deviation of the Response Factor (RSD of RF %) is the measure of the linearity of the response factors for each compound in the calibration curve, where the response factor is a measure of the relative response (ion count) of an analyte compared to that of an internal standard. Calibration will be conducted in accordance with the procedures described in detail within the HAPSITE™ Operation Manual attached to the SAP. R^2 is the coefficient of determination or correlation coefficient squared and measures variation in the y variable attributable to the x variable. In the case of instrument calibration, this is the instrument reading relative to the known concentration of a calibration standard.

Prior to the daily analysis of samples and blanks, but after tuning criteria and initial calibration have been met, the initial calibration of the GC/MS system must be routinely checked by analyzing a continuing calibration verification (CCV) standard to ensure that the instrument continues to remain within control limits. The CCV standard will be performed once every 24 hours.

The initial equipment checks and QA analyses will be performed using a project-specific method and calibration library provided onboard the instrument. If the QA results fall outside of the desired performance goals, the instrument will be recalibrated.

In the event a sample concentration overwhelms the HAPSITE™ (i.e., concentrations completely saturate the detector as indicated by analytical results), the instrument will require purging of the analytical system with nitrogen in accordance with the Operators Manual to clean the detector before the next sample can be analyzed. Purging shall continue until the instrument results (blanks) indicate the no carry-over concentrations remain.

5.3 Storage and Routine Maintenance

The HAPSITE should be stored in a climate-controlled, dry location where it can be plugged into a stable power outlet and left in “Stand-by” mode – even over weekends. The use of Stand-by mode maintains the system temperature and carrier gas pumps and preserves the system calibration so that daily startup times are considerably shorter. A properly stored HAPSITE in standby mode can maintain its reliability and calibration for up to a month.

The routine maintenance schedule of the HAPSITE is described in the QAPP and in the Operators Manual. Key maintenance includes switching tuning standard cylinders and performing self-test programs before beginning sampling. The internal power source (battery) for the HAPSITE™ provides only two to three hours of operation time and, except when using the instrument in Survey Mode, the HAPSITE should be placed on the floor or on a cart and connected to external electrical 110 Volt AC power.

6.0 Outdoor Real-time Qualitative Sampling

After confirming that the HAPSITE™ meets tuning and continuing calibration requirements, and upon arrival at a testing site, the HAPSITE™ shall be operated in Analyze Mode to collect an ambient outdoor background sample. The sample is acquired in order to define the ambient (outdoor) concentration of the target VOCs.

The outdoor quantitative sampling should be conducted upwind, but within 10 to 30 feet of the structure to be assessed. The sample is collected upwind of the building at a height of approximately three to five feet above the ground surface (approximating the breathing zone). Outside weather conditions shall be recorded including temperature, barometric pressure, wind direction, and an estimate of wind velocity (categorical).

7.0 Identification of Interior Background Sources

Consumer products and household items are commonly found to be significant sources of chlorinated VOCs in indoor air (see Table below).

CHEMICAL[1]	GENERAL CATEGORIES
1,2-DCA	Molded plastic products, air fresheners
Carbon Tetrachloride	Aerosol cans, refrigerants, dry cleaned clothes, varnish
Chloroform	Dry cleaned clothes, fire extinguishers, adhesive remover, chlorinated drinking water
PCE	Dry cleaned clothes, automotive brake cleaners, metal degreasers, hobby craft glue
TCE	Self-defense pepper spray, degreaser, rug-cleaners
Trans-1,2-DCE	Taxidermy foam, refrigerants, cleaning solutions
1,1,1-TCA	Cleaners, adhesives, aerosol cans

1) Data sources: U.S. Department of Health and Human Services. Household Products Database. 2012.

After collecting a quantitative outdoor ambient background sample, the HAPSITE™shall be switched to operate in Survey Mode inside the building to identify the presence of any elevated VOC concentrations. The initial indoor survey should be conducted by walking through the structure room-by-room (or groups of openly connected rooms) while holding the HAPSITE™ probe at waist level and observing instrument responses (ion count). The initial room to room survey will be followed by localized (sub-areas of rooms) assessments as indicated by initial results to identify and record locations of interior background sources.

The indoor source identification procedure involves using a combination of continuous-read qualitative analysis in survey mode, visual inspection, and isolation. In continuous-reading survey mode, the instrument is used to scan potential sources for the specific target analytes. In survey mode, scan near storage units (e.g., cabinets, closets, storage containers, etc.) and product containers found in the room(s) with the highest concentration of the target VOCs detected during the initial survey and quantitative testing. As the potential source area is approached, the ion counts on the instrument will increase. If an instrument response is observed for a storage unit such as a cabinet or drawer, with permission of the property representative, examine the unit for products or materials. Examine the product labels to see if

the target VOC is identified on the label and note the type of product on the sampling record. Do not remove the products, return the unit to its as found condition, and proceed with the assessment. If permission is not granted to inspect a storage unit, the area will be noted as a possible source of background contamination. *[Note that the procedures outlined in the previous two paragraphs have been updated in MFM #4 and #8 (Attachment 1B and 1C, respectively). The indoor air will be analyzed for VOCs using the field portable GC/MS in quantitation mode. Screening will be conducted on each level (basements and living/working floors. If VOCs are detected, the portable GC/MS will be run in survey mode to aid identification of background sources of VOCs such as chemical products and dry-cleaned clothing. If such sources are found, the resident will be asked to relocate the materials from the occupied structure to prepare for real-time air assessment (MFM #4 and #8 (Attachments 1B and 1C, respectively)).]*

Locations of identified indoor sources will be recorded on the electronic sampling forms and rooms with elevated VOCs not tied to an indoor source shall be noted for further investigation for vapor intrusion points.

8.0 Survey of Potential Vapor Intrusion Entry Points

Areas identified in the initial VI assessment inspection and during the initial walk-through of the structure for potential vapor intrusion entry points will be assessed using the HAPSITE™ in survey mode. The vapor intrusion entry survey will be concurrent with the indoor source survey to the extent practical.

The instrument will be used to scan potential vapor entry points such as sumps, floor drains, expansion joints, plumbing penetrations, or foundation cracks. The sampling port is placed near the potential vapor entry point. If the ion counts increase in the vicinity of the entry point, then there is evidence that there is a vapor intrusion problem. In addition, any VOCs identified by type by the instrument will be recorded. The particular room (or rooms) shall be further evaluated in quantitative mode under depressurization conditions.

9.0 Initial Real-time Quantitative Sampling

After the initial Survey for indoor background and vapor intrusion points for target VOCs has been completed, the HAPSITE™ shall be switched to Analyze Mode to conduct real-time quantitative indoor air sampling and analysis (under ambient pressure conditions). Based on the structural assessment, floor plan of the structure, and Survey Mode results, an initial indoor sample for quantitative analysis will be collected from the three to five foot high breathing zone interval in each major floor level within the building; for example, the basement, main floor, and second floor of the structure. Additional samples may be collected from potential indoor source areas such as an attached garage and from specific rooms where the initial survey indicated evidence of elevated VOCs.

If the concentration of the target VOCs in all areas is below detection limits or below the screening action level concentrations, then it can be concluded that there are no significant background sources of indoor air contamination. The assessment then proceeds to performing an indoor air assessment under negative pressure conditions (Section 10.0). If target VOCs in one or more major areas are detected above screening levels, then a more detailed quantitative assessment is performed to determine the specific rooms associated with the areas exhibiting the highest concentrations. For example, if the VOC concentrations from the first round of sampling were highest in the basement, each room in the basement would be

sampled in quantitative mode.

10.0 Negative Pressure Real-Time Quantitative Sampling

Building depressurization (negative pressure) can exacerbate a vapor intrusion problem and may be a conservative means of detecting vapor intrusion within a structure. The structure will be placed under a stable differential pressure of -5 pascals using a variable speed louvered air door installed in a doorway located at the lowest possible level at the structure. A recording digital manometer will be used to measure the indoor versus outdoor pressure differential and the structure will be maintained under negative differential pressurization for 30 minutes (or until at least 2.5 air exchanges have occurred) before initiating sampling. The louvered air door to be employed in the depressurization will be capable of exhausting up to 6,000 cubic feet per minute of air; however, depending on construction tightness of the structure, particularly in homes built prior to the 1970s, air leakage into the home may not allow attaining of the -5.0 pascal target depressurization level. In this case, testing will proceed as long as any differential depressurization can be achieved. In the event the structure does not achieve a one pascal depressurization relative to the outdoors, this will be taken as an indicator that the structure construction is so leaky with respect to outdoor air that depressurization does not naturally occur and will be noted on the sampling forms, and the sampling will continue to verify that no increases in concentrations occurred..

The HAPSITE™ will be deployed in Analyze Mode in a high-risk location (defined as the lowest living or occupied level of a structure and where vapor intrusion is most likely to occur) immediately prior to the start and operated continuously (one sample every eight minutes or as often as instrument cycling allows) during negative pressurization until the 2.5 air exchanges have been attained. Upon achieving conditions stated above, additional quantitative sampling will be performed on every level of the structure, in the same locations used during the ambient characterization. If the previous entry point screening using the HAPSITE™ in Survey mode identified an area of probable vapor intrusion, then a quantitative measurement will be performed in that room while it is under negative depressurization.

It is important to note that the residences and structures to be tested range in size from single floor dwellings to large public buildings and range in age from 30 to over 100 years. In the event that an entire structure cannot effectively be placed under negative pressure due to size, floor plan layout, or extreme air leakage, the blower door will be located to depressurize the lowest level of the structure where vapor intrusion is most likely to occur, as indicated by the previous testing results. The final decision will be made by the field team leader, and the decision rationale noted in the electronic field record.

11.0 Positive Pressure Real Time Quantitative Sampling

Building pressurization (positive pressure) can assist in the differentiation of indoor background sources and actual vapor intrusion. The structure will be placed under a stable differential pressure of +5 pascals using a variable speed louvered air door installed at the same location as used for the negative depressurization discussed in Section 10.0. In addition, if the initial indoor source survey and ambient quantitative analysis results suggest an indoor source on an upper level, the pressurization test will be conducted with the blower door installed on that level. A recording digital manometer will be used to measure the indoor versus outdoor pressure differential and the structure will be maintained under positive differential pressurization for 30 minutes (or until at least 2.5 air exchanges have occurred) before initiating sampling. Testing will proceed as long as any differential pressurization can be achieved. In the event the

structure does not achieve pressurization relative to the outdoors, the building will be assumed to be too leaky to pressurize and any reduction in vapor concentrations is the result of fresh air dilution.

The HAPSITE™ will be deployed in Analyze Mode in a high-risk location (defined as the lowest living or occupied level of a structure and where vapor intrusion is most likely to occur) immediately prior to the start and operated continuously (one sample every eight minutes or as often as instrument cycling allows) once positive pressurization is achieved until the 2.5 air exchanges have been attained. Upon achieving conditions stated above, additional quantitative sampling, at a minimum, will be performed on every level of the structure, in the same locations used during the ambient characterization. If the previous entry point screening using the HAPSITE™ in Survey mode identified an area of probable vapor intrusion, then a quantitative measurement will be performed in that room while it is under positive pressurization.

It is important to note that the residences and structures to be tested range in size from single floor dwellings to large public buildings and range in age from 30 to over 100 years. In the event that an entire structure cannot effectively be placed under positive pressure due to building size, floor plan layout, or extreme air leakage, the blower door will be located to pressurize the lowest level of the structure where vapor intrusion is most likely to occur, as indicated by the previous testing results, and secondly, in the area noted as most likely containing indoor source materials. The final decision will be made by the field team leader, and the decision rationale noted in the electronic field record.

12.0 SUMMA™ Canister Sampling

Laboratory confirmation samples will be collected from structures where any quantitative HAPSITE ambient indoor or quantitative HAPSITE™ depressurization analyses exceed the screening action levels for any target VOC. Sample collection will use a 24-hour composite sample from a SUMMA™ canister and will be analyzed by Method TO-15.

For residences or other occupied buildings meeting this criteria, at least one indoor air sample for lab analysis will be collected per building. This sample will typically be collected in the lowest regularly occupied level of the home (either a finished basement or first floor) in contact with the ground. If the specific construction or configuration of a residence suggests one indoor sample will not be representative, or field-based detections of any contaminant of interest are detected in widely separated multiple locations, then a second indoor air sample may be collected from another living space, working space, or an unfinished basement room, as indicated by HAPSITE™ characterization results. A house or dwelling's heating and cooling systems can be used during the SUMMA™ Canister sampling.

Non-residential structures such as school buildings and businesses will be screened for indoor air sources, vapor entry points, and negative/positive pressurization as described above, and SUMMA™ canister sample locations will be selected based on the uses of the lower levels of the structure or where VI is most likely to occur. In particular, basement level classrooms in school buildings may be tested with SUMMA canisters for lab analysis regardless of the HAPSITE™ results.

In addition, at least three structures that exhibit concentrations below screening levels (including at least one location with no HAPSITE™ detection of target VOCs) will be sampled using 24-hour SUMMA canisters.

The indoor air samples for full laboratory analysis will be collected into laboratory-supplied six-liter SUMMA™ canisters over a 24-hour period, as detailed below:

- A clean and inerted six-liter Summa canister under a 25 in. Hg vacuum equipped with a flow regulator will be placed at a height of three to five feet above the floor in the center of the space to be sampled.
- The flow regulator will be set to collect a 24-hour time weighted sample (approximately 4 ml/min).
- Sampling will be stopped (i.e., the valves closed and the canister disconnected) after about 24 hours once the vacuum reaches about 5 in. Hg).
- The sampling crew will record the sample name, initial and final vacuums, initial and final sampling times, canister and flow controller serial numbers, and other pertinent information on the field sampling summary and laboratory Chain of Custody (CoC) forms.
- Canisters will be packed in a rigid wall shipping container, such as a cooler or heavy-duty cardboard box (ice is not required), if shipping is required.
- A custody seal will be placed over the openings to the shipping container.
- The shipping container will be shipped or delivered immediately to the laboratory for analysis.
- All samples will be accompanied by the CoC as described in the QAPP.

SUMMA™ Canister sampling will be conducted in accordance with the SOPs provided in the SAP.

As an additional confirmation on the accuracy and precision of the HAPSITE™, up to six instantaneous SUMMA™ grab samples will be collected and analyzed for TO-15 parameters in residences where VOCs are detected during the HAPSITE quantitative sampling. The grab samples will be co-located with the HAPSITE™ sample probe and collected by opening the SUMMA™ canister valve to allow the canister to fill concurrently with the HAPSITE sample intake process. The results will represent the VOC concentrations present at a given location at the time of collection and can be correlated compared directly to HAPSITE quantitative results similar to a duplicate sample analysis.

13.0 Near-Slab Real-Time Soil Gas Sampling and Analysis

The near-slab soil gas characterization approach will be implemented concurrent with the indoor air characterization to identify and characterize target VOCs present in soils adjacent to tested structures. The purpose of the soil gas sampling is two-fold (1) provide soil gas concentrations near structure foundations for support of the AOU-1 Vapor Intrusion Risk Assessment pathway evaluation process; and (2) provide information to help define the potential extents of the underlying groundwater VOC plume.

Near-slab soil gas characterization will be performed adjacent (within five feet) to all structures screened and assessed for indoor vapor intrusion. Soil vapor probes will be driven adjacent to the structure's foundation to a depth approximately six inches below the base of the foundation or to the top of the water table, whichever occurs first. Samples will be collected with a peristaltic pump and Tedlar® bags, field screened with a PID and multi-gas meter, then a second sample collected in the same manner and field-screened in real-time with the portable GC/MS in analyze

mode to identify and quantify any target VOCs present in soil pore space adjacent to structures. At locations where groundwater is not encountered at the base of the foundation, after sampling, the probe rod will be driven another five feet, if soil conditions allow, and the sampling process repeated to obtain vertical delineation data for soil gas. If groundwater is encountered, the approximate depth-to-water will be measured and recorded, the probe re-installed to just above the water table, and a soil gas sample collected just above the water level.

Soil gas samples will also be collected in SUMMA™ canisters and analyzed for full volatile organics (TO-15) analysis for any near-slab characterization sample where indoor SUMMA™ canisters are collected. *[Note that MFM #4 and #8 (Attachments 1B and 1C, respectively) state: collect soil gas samples in a Summa canister and submit selected soil gas samples for full volatile organics (TO-15) analysis at a UDOH certified laboratory at any location where a near-slab characterization sample exceeds the 11.0 µg/m^3 (1.62 ppbv) SL for PCE or where soil gas vapors are found to be elevated 10 times the RSL for the detected VOC. Note however, this screening value was corrected to 370 µg/m^3 (54.55 ppbv) in QAPP Revision 2 (VA 2017).]* In addition, three selected locations throughout AOU-1 where the field portable GC/MS did not detect target VOCs in soil gas above screening levels will be sampled. Sampling for laboratory analyses will be accomplished using SUMMA™ canisters equipped with flow regulators to collect 24-hour time-averaged samples from the soil vapor probes.

In addition to confirmatory VOC analyses, five percent of the soil gas sampling locations within the PCE plume area will be selected for additional Semi-Volatile Organic Compound (SVOC) analyses using method TO-13A. Method TO-13A employs laboratory-supplied sorbent tubes attached inline between the vapor probe and a vacuum pump set at a flow rate of 5 L/min for 480 minutes (8 hours). SVOC samples are for informational purposes to support full characterization of the plume nature and extent, and possible future risk assessment of the Site. *[Note that MFM #3 (Attachment 1B) indicates that no samples will be analyzed using method TO-13. Additionally, per MFM #4 and #8 (Attachments 1B and 1C, respectively) soil gas samples for TO-15 analysis will only be collected if soil gas PCE concentrations exceed the 11.0 µg/m^3 (1.62 ppbv) SL or where soil gas vapors are found to be elevated 10 times the RSL for the detected VOC. Note however, this screening value was corrected to 370 µg/m^3 (54.55 ppbv) in QAPP Revision 2 (VA 2017).]*

The procedures for emplacing the soil gas probes, testing the integrity of the seal, and for collecting and analyzing samples both for the HAPSITE™ and the TO-15 Method and TO-13A Method are described in the QAPP (Section 2.3.2) and the SAP (Section 5.4).

14.0 Data Management and Distribution

14.1 Data Management

Information that will be included in the project data record relative to the indoor air study include field log books, sample collection and handling records, operational records, GPS data, chain-of-custody forms sample receipt records, and shipping documentation. Field log books may be kept electronically via hand-held tablets.

The project field team leader will be required to maintain a field logbook of daily activities. A separate logbook of suitable material that will be bound with consecutively numbered pages will be used for this project. All entries will be legibly written in black ink. Any entry errors are corrected by drawing one solid line through the incorrect entry followed by the user's initials and date. The bottom of each page is signed and dated by the individual making the entries. Factual and objective language will be used. All entries will be complete and accurate enough to allow

reconstruction of each field activity. Activities should be recorded contemporaneously.

The field logbook cover will include the following information:

- job name, contract, and delivery order numbers,
- site activity name,
- start date,
- end date of last logbook entry.

Daily entries of the following minimum information will be recorded in the logbook as follows:

- date and time, expressed in 24-hour (military) format;
- sampling start/stop times;
- weather conditions;
- personnel present;
- field observations;
- site identification and building layout (visual sketches where appropriate);
- location of sampling points (GPS coordinates and/or visual sketches where appropriate);
- description of sample;
- sample identification number;
- number of samples taken;
- time of sample collection;
- number of Quality Assurance/Quality Control (QA/QC) samples taken;
- type and mode of field instrumentation;
- names of people collecting samples;
  all calibrations done;
- any other field instruments;
- any general observations or notes;
- any deviations from the sampling plan.

Sample custody will be documented on standardized CoC records, an example of which is included in Attachment 3 of the QAPP. The CoC record establishes the documentation necessary to trace sample possession from time of collection through sample analysis and final disposition. A sample is in the custody of a person if any of the following criteria are met:

- the sample is in a person's physical possession;
- the sample is in a person's view after being in his or her physical possession;
- the sample was in a person's physical possession and was then locked up or sealed to prevent tampering; and/or
- the sample is kept in a secured area.

Field forms including soil gas sampling data sheet, indoor air sampling data sheets, HAPSITE calibration, and QC information will be used during field work. Examples of these forms can be found in Attachment D of the QAPP.

Photographs will be taken in the field to document sampling locations and conditions. Digital camera photographs will be taken with the date/time record turned on. Photographs of all sampling locations will be taken with the sample number. A photographic log will be kept in

which the date, location, photographer's name, and direction the photographer is facing (if appropriate) will be recorded. Photographs will be labeled, placed in a binder or stored electronically, and submitted at the end of the field work. Selected photographs will be used in reports as deemed necessary or appropriate.

14.2 Data Distribution

Data distribution, in the form of reports and memos, are described in the QAPP (Section 4.2) and are summarized below:

- *Weekly Field Status Reports* – Communicates to VA Remedial Project Manager (RPM) weekly progress and any significant preliminary findings, QA/QC issues, and changes to the field schedule.
- *Progress Reports* – Communicates the progress made by VA and its consultants on a monthly basis regarding site investigation, community involvement, achievement of project milestones, and the myriad of actions that encompass the investigation of AOU-1.
- *Environmental Media Reports* – Communicates in brief the conclusions of individual investigation events (Indoor Air, Soil Gas, Surface Water, and Groundwater) for AOU-1 and any laboratory analysis associated with the event. These reports will be written by the Program Manager and submitted to the VA RPM, EPA, and Utah Department of Environmental Quality (UDEQ).
- *Nonconformance Reports* – Identifies any deviations of planned or expected scope-of-work activities relating to the investigation of AOU-1. Reports may pertain to field data collection, health and safety events, etc. These reports will be written by the FET Program Manager or QA Manager. The reports will be submitted to the VA RPM and Quality Assurance Manager, and if needed, the EPA and UDEQ.
- *Laboratory Audits/Corrective Action Reports* – Communicates the result of any third-party audit or review of the analytical laboratory that is supporting the FET investigation activities. This report will be written by the CLP (soil and water media results) and ALS Global Labs (soil gas and air) laboratory designated personnel. The reports will be submitted to the FET Program Manager, VA RPM and Quality Assurance Manager, UDEQ RPM and the EPA RPMs.
- *Remedial Project Managers (RPM) Debriefings* – Weekly conference calls between VA, EPA, UDEQ and other key stakeholders to discuss previous week's field efforts and investigation.
- *Data Validation Reports* – Communicates the results of laboratory data validation for each media (indoor air, soil gas, surface water, and groundwater) to VA, EPA, and UDEQ. Each report will provide a summary of the data validation process, a list of analytes having changed data qualifiers, a list of analytes rejected during validation, and a determination of the usability of the data. The data validation reports will be prepared by the FET lead data validator and the QA/QC Manager.
- *Remedial Investigation Report (RI Report)* – Communicates the conclusions of all investigation events for AOU-1 and any laboratory analysis associated with the event. The RI Report will also contain summaries of data validation reports and deviations from the SAP and QAPP.

RIWP Minor Field Modification-01
Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments
700 South 1600 East PCE Plume Superfund Site
Salt Lake City, Utah

PREPARED FOR: D. Lynne Welsh, VA Salt Lake City Health Care System

PREPARED BY: Ed Reid, First Environment, Inc.

COPIES: David Waite, CH2M-Hill; Rolf Lange, Avalon; Devin DeMarco, Ellen Reid, First Environment, Inc.

DATE: July 17, 2015

Introduction

This document provides a description of a minor modification to the Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments, Version 4.0 (dated December 23, 2014) for the use of real-time on-site gas chromatography/mass spectrometry (GC/MS) analysis to evaluate the potential for vapor intrusion in structures associated with the Accelerated Operable Unit-1 (AOU-1) portion of the 700 South 1600 East PCE Plume (Plume). The protocol is included as Appendix H of the RIWP. The minor modification is a result of lessons learned during implementing the protocol in early January 2015, additional field training with the field-portable GC/MS (HAPSite™), and the initial screening using the protocol at a variety of sites during the first four weeks of the field effort.

The changes to the protocol are primarily changes in the order of various components of the indoor air screening process. In addition, further clarification to the quantitative indoor ambient air testing process to better define the location and number of rooms to be tested per floor level are provided.

Indoor Air Screening Process Modification

The current Protocol provides general procedures in Sections 7.0, 8.0, and 9.0 for conduct of initial qualitative (HAPSite™ in survey mode) screening for indoor background sources, conduct of initial qualitative (HAPSite™ in survey mode) vapor entry point screening, and conduct of quantitative (HAPSite™ in analyze mode) indoor ambient air sampling, respectively. This portion of the testing is done under ambient conditions. Currently, immediately upon entering a site, the HAPSite™ is used to conduct surveys throughout the building to identify potential locations of indoor background source materials and potential locations of vapor entry. Then, based on the surveys, the HAPSite™ is used in analyze mode to quantify concentrations on each floor of the structure and in habitable rooms.

After testing a number of buildings, it is apparent that walking through a site room-by-room with the HAPSite™ in survey mode is inefficient due to the lack of elevated indoor sources above the survey mode detection limits of about 100 ppb in nearly all structures. Below the survey mode

detection limits, the team can only record total ion counts (TICs) relative to baseline TIC to obtain a gross representation of target compounds. In addition, the vapor entry survey has rarely assisted in identifying entry points when random surveys of cracks, wall penetrations, and crawl spaces have been performed in survey mode. Quantitative testing of ambient air has proven to be better at providing initial data that allows the HAPSite™ operator to isolate specific rooms or areas of a site for further evaluation of indoor sources and entry points.

The original Protocol should be changed so that the order of indoor air testing begins with ambient indoor air analysis (Section 9.0) and then proceeds with either indoor background source surveys (Section 7.0) based on ambient results and visual observation of source materials, or vapor entry point surveys based on ambient results and observations of potential entry points.

The regulatory agencies (EPA and UDEQ) verbally agreed to the change on February 5, 2015 and effective upon VA acceptance of the Minor Field Modification, the Protocol is modified so that ambient indoor air analysis will be conducted upon entry into a site. Ambient air samples will be collected and analyzed by the HAPSite from each occupied level of the site and from selected representative rooms or areas on each level. In addition, the operator will collect ambient samples from selected spaces (i.e., closets, utility rooms, and crawl spaces accessed via entry doors from the basement areas) where indoor source materials may be present. Rooms or spaces with notable potential entry points (i.e., large floor cracks, open sump pits, floor drains, exposed sub-slab soil) will also be tested to determine ambient air concentrations within the space.

Upon completion of ambient air sampling and analysis with the HAPSite™, the operator will evaluate the initial ambient results and, in conjunction with visual observations of potential source materials, will switch the HAPSite™ to survey mode and run short (2-3 minute) surveys at locations where indoor sources are more likely to be present, as discussed in the Protocol. TICs will be noted during each survey and the specific item provoking the response also noted, if any. If ambient quantitative data indicates target compounds were below the HAPSite™ detection limits (approximately 0.1 ppbv) and no source materials were observed, then an indoor source survey is not necessary and shall be noted on the VI field forms. If ambient quantitative data shows target compound concentrations just above detection limits from a structure level where only one or two representative samples were initially collected, additional ambient samples will be collected from other locations (at least one other location) throughout that level to verify concentrations do not increase in other portions of the level – as a result of an indoor source.

After indoor source surveys are complete or deemed un-necessary, the operator will use the ambient-results evaluation and previous visual observations of potential vapor entry points to select locations to survey for vapor entry. The HAPSite will be used in survey mode as described in the original protocol and 2-3 minute surveys at suspected entry points (typically sumps, floor drains, foundation wall penetrations, and bare soil crawl spaces). TIC response will be noted and the type of entry and location also noted. If ambient quantitative data indicates target compounds were below or just above the HAPSite™ detection limits (approximately 0.1 ppbv) and no potential entry points were observed, then a vapor entry survey is not necessary and shall be noted on the VI field forms.

DATE: 2 March 2016

SUBJECT: Minor Field Modifications to the Remedial Investigation Work Plan AOU-1: East Side Springs 700 South 1600 East PCE Plume Salt Lake City, Utah (July 2015)

1. Introduction

This document provides a description of minor modifications to the Remedial Investigation Work Plan (RIWP) AOU-1: East Side Springs 700 South 1600 East PCE Plume Salt Lake City, Utah (July 2015) to provide consistency for sampling methods, analytes, and other details documented in the RIWP and the Quality Assurance Project Plan (QAPP) Update Revision 1. Minor Field Modification #1 Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments and Minor Field Modification #2 Clarification of QAPP Amendment Number 1 are included in the Final RIWP as Appendices K and L. The following modifications are detailed below:

- Minor Field Modification #3 – Change of analytical method for analysis of 1,4-dioxane (EPA Crosswalk[1] items A6(a)(iii), A6(a)(vii), B1(b), B1(c), B2(a)(i), B2(b), B2(f)(ii), B2(h), B2(i), B3(a)(i), B3(b)(i), B3(d)(i), B4(b)(i), B4(c)(i), B5(a)(i), B6(b), B7(a)(i), B7(b)(i), B8(a)(ii))
- Minor Field Modification #4 – Updates to the analytical methods, parameters, and the sample media on which the analyses will be performed; updates to number of samples, sample locations and depth, analyses, collection methodology, etc. for each of the targeted media; change in use of HAPSITE gas chromatograph/mass spectrometer for field screening of groundwater and surface water samples (EPA Crosswalk[1] items A6(a)(ii), A6(a)(ix), A6(a)(x), A6(a)(xi), A6(a)(xii), B1(f)(i), B1(f)(vi))
- Minor Field Modification #5 – Update of Health and Safety Plan (HASP) (Appendix C of RIWP)
- Minor Field Modification #6 – Inclusion of isotope analysis of surface water (EPA Crosswalk[1] items A3, A4(a)(iii), A4(e), A6(a)(x), A9(a), B4(a)(ii), B4(f))

2. Minor Field Modifcation #3

The TO-15 SIM analyte list will include 1, 4-dioxane. Therefore, TO-13 sampling and analysis will not be used for any samples collected during the 2016 sampling event. This field modification is a change to sections 6.2.1.3 and 6.2.2.2 of the RIWP.

3. Minor Field Modifcation #4

The following sections and table from the RIWP have been updated for consistency with the QAPP Update Revision 1 with respect to 1) analytical methods, parameters, and the sample media on which the analyses will be performed; 2) number of samples, sample locations and depth, analyses, collection methodology, etc. for each of the targeted media; and 3) change in use of HAPSITE gas chromatograph/mass spectrometer for field screening of groundwater and surface water samples.

Section 6.2.1 Indoor Air Quality Assessment is hereby replaced with QAPP Update Revision 1 Section 2.3.1 as follows:

The indoor air characterization approach is as follows:

- *Indoor Air Screening step: Access each occupied structure within AOU-1 where the occupant/owner has granted access and complete visual inspection for potential indoor VOC sources and conduct resident interview. The indoor air will be analyzed for chlorinated volatile organic compounds (cVOCs) using the field portable GC/MS in quantitation mode. Screening will be conducted on each level (basements and living/working floors. If cVOCs are detected, the portable GC/MS will be run in survey mode to aid identification of background sources of cVOCs such as chemical products and dry-cleaned clothing. If such sources are found, the resident will be asked to relocate the materials from the occupied structure to prepare for real-time air assessment. It is estimated that as many as 300 occupied structures, including residences, schools, daycare facilities, and other businesses, are within the AOU-1 boundaries; however, participation of owners will likely be much less and reduce the actual testing locations, with 30 to 50 structures estimated to be included in the testing.*
- *Indoor Air Characterization step: Conduct real-time assessment of indoor air quality at accessible occupied structures within the AOU-1 area where permission has been obtained. The characterization of indoor air will occur in the breathing zone under both ambient conditions approximately 30 minutes after the indoor source screening step is completed and then after the structure is placed under negative differential pressurization (target differential pressure of 10 pascals, equivalent of 0.04 inches of water, a level that replicates the effects of typical cold season stack effects, between inside and outside) as measured with a portable field manometer. Each structure for which access has been granted within AOU-1will be evaluated for cVOCs, using the portable GC/MS in analyze mode, with testing occurring within the breathing zone on basements and living/working levels of the structure to identify the compounds present in the indoor air. A properly calibrated portable GC/MS in analyze mode is capable of achieving low ppbv to parts per trillion by volume detection limits for PCE and TCE in air. The portable GC/MS will also be used in analyze mode to measure ambient outdoor background concentrations concurrent with the indoor activities. To the extent practical given site access considerations and variable wind directions over the period of sampling, one outdoor air sample will be collected associated with each structure.*
- *Indoor Air Verification step: Conduct indoor air sampling using Summa canisters equipped with flow regulators to collect 24-hour time-averaged samples in structures where concentrations of the 5 PCOPCs exceed the screening levels shown in RIWP Appendix H. Concurrent measurements for differential air pressure (inside and outside) will be taken during this step to*

assure samples are representative of conditions that create vapor intrusion. Samples will be sent to a Utah Department of Health (UDOH)-certified laboratory for volatile organic compound (VOC) analysis or VOC-Selective Ion Monitoring (SIM) analysis to achieve lower reporting limits for PCOCs using the EPA Toxic Organics (TO)-15 analytical method. Laboratory testing of indoor air is estimated to occur at approximately 25 structures out of the 30 to 500 expected to be initially assessed in the AOU-1 area, and analysis of up to 40 indoor samples is expected (some structures will require multiple sample locations). Based on Minor Field Modification #1, an additional 4 structures will be sampled to aid the assessment of whether vinyl chloride is present at concentrations below the detection limit using the portable GC/MS. This is needed because the vinyl chloride reporting limit using the portable GC/MS is above the screening level, whereas, the reporting limit for laboratory samples is below the detection limit. The selected structures will be located where groundwater is within 10 to 20 feet of the ground surface and will include:

- *One sample outside the Plume where PCE, TCE, and cis-DCE in the indoor air are below the screening levels (SLs) or the detection limit of the HAPSITE® instrument.*
- *Three samples will be collected inside the area of the Plume where PCE and TCE are equal to or less than their respective SLs but above the instrument detection limits.*

At least three outdoor (upwind, downwind, and in the center of AOU-1) ambient background samples will be collected during the confirmation sampling activities for laboratory analysis for VOCs using method TO-15.

- *Additional Monitoring Activities: In addition to the initial screening, which will be conducted under cold season and low water table conditions, a second round of assessment and confirmation sampling of indoor air at up to 15 selected outdoor background and indoor air locations, based on the potential for indoor air exposure, will be conducted during Spring 2016. This phase will be conducted in the vicinity of known PCE contamination based on results from the initial sampling. The area of AOU-1 where PCE was previously detected above the screening level in indoor air samples and shallow groundwater is anticipated is known as the focus area. The re-testing will be conducted using both real-time field analyses (portable GC/MS) and confirmatory laboratory analysis using Summa canisters for sample collection and offsite laboratory analysis.*

Section 6.2.2 Near-slab Soil Gas Investigation is hereby replaced with QAPP Update Revision 1 Section 2.3.2 as follows:

The near-slab soil gas characterization approach will be implemented concurrent with the indoor air characterization to identify and characterize cVOCs present in soils adjacent to tested structures, as follows:

Near-slab Soil Gas Characterization step: Conduct soil gas characterization adjacent to structures screened and assessed for vapor intrusion where the property owner agreed to soil gas sampling and sampling is practical given site conditions. Soil vapor probes will be driven adjacent to the structure foundation to a depth approximately 6 inches below the base of the foundation or to the top of the water table, whichever occurs first. Samples will be collected with a vacuum pump and Tedlar® bags, field screened with a photoionization detector (PID) and

multigas meter, then a second sample collected in the same manner and field-screened with the portable GC/MS in analyze mode to identify and quantify any cVOCs present in soil pore space adjacent to structures. At locations where groundwater is not encountered at the base of the foundation, the probe rod will be driven another 5 feet after the initial sample is collected, if soil conditions allow, to obtain another sample for vertical delineation data for soil gas. If groundwater is encountered, the approximate depth to water will be measured and recorded. It is anticipated that up to 50 locations will be field screened for near-slab soil gas concentrations during the study.

- *Near-slab Soil Gas Characterization Verification step: Collect soil gas samples in a Summa canister and submit selected soil gas samples for full volatile organics (TO-15) analysis at a UDOH certified laboratory at any location where a near-slab characterization sample exceeds the 11.0 µg/m^3 (1.62 ppbv) SL for PCE or where soil gas vapors are found to be elevated 10 times the RSL for the detected VOC. In addition, selected locations where the field portable GC/MS did not detect VOCs in soil gas will be sampled to confirm results. Sampling for laboratory analyses will be accomplished using Summa canisters equipped with flow regulators to collect 24-hour time-averaged samples from the soil vapor probes. Based on the expected number of buildings located within the area where soil gas impact caused by the PCE plume is most likely to occur, laboratory testing of soil gas is estimated to occur at up to 15 locations.*

- *Conduct additional near-slab, soil floor and crawl space for TO-15 analysis, using a UDOH certified and EPA-approved laboratory, at structure locations identified during the indoor air field characterization and during the field investigation as having high potential for vapor intrusion into indoor air. These locations are proposed to provide additional high-quality lab data for human health risk assessment resulting from the vapor intrusion pathway.*

Near-slab testing was chosen in lieu of sub-slab testing due to the presence of extremely shallow groundwater that occurs at or very near the slabs of many residences as indicated by numerous sump pumps and discharging footer drains. The likelihood of causing groundwater to leak into the basement of a structure by penetrating the slab to install testing apparatus was deemed too risky by the project team.

The indoor air assessment/characterization and near-slab soil gas sampling will commence at the same residences or occupied structures where owners have already indicated they will allow indoor air testing, and then pending permission to access additional properties, proceed to structure locations adjacent to the previously identified springs and seeps. It is anticipated that additional property owners may need to be actively recruited by VA in some portions of AOU-1 to fill data gaps, but at least 36 owners have already indicated a willingness to allow testing. The initial locations for indoor air and soil gas sampling are shown on Figure 9.

Section 6.2.3 Open-field Soil Gas Investigation is hereby replaced with QAPP Update Revision 1 Section 2.3.3 as follows:

Open-field soil gas data will be collected to provide a means of estimating the plume impacted area and to aid in evaluation of vapor intrusion potential. Concurrent with or immediately following the initial indoor air quality characterization steps and near-slab soil gas characterization, the investigative sampling approach for open field soil gas will proceed as follows:

- *Conduct field screening of soil gas levels and vertically profile the soil gas concentrations of PCE and daughter products in the vadose zone by manually or mechanically installing unsaturated (vadose) zone soil vapor sampling points near historically cVOC-impacted seeps and*

springs and in selected locations adjacent to streets/sidewalks (open field samples) in AOU-1. The field screening will be conducted by collecting soil gas samples in Tedlar bags for subsequent analysis using the field portable GC/MS equipment or the GC/MS probe will be connected directly to the sampling point. It is anticipated that soil gas samples will be collected from locations adjacent to the six spring identified during the previous investigations that contained PCE; then at the six spring locations that did not contain PCE; and then expand the sampling program to additional spring locations within AOU-1 as they are identified during field activities, up to an expected total of 50 samples.

- *Conduct additional open field soil gas sampling for TO-15 analysis, using a UDOH certified and EPA-approved laboratory.*

The open field soil gas sampling (near seeps or springs and along public right of ways) will commence at residences or occupied structures where owners have already indicated they will allow access for indoor air testing, and then pending permission to access, proceed to structure locations adjacent to the previously identified springs or seeps, and at selected locations on public rights of way.

Section 6.2.4 Surface Water and Shallow Groundwater Investigation is hereby replaced with QAPP Update Revision 1 Section 2.3.4 as follows:

Concurrent with or immediately following the initial indoor air quality characterization steps, the general investigative sampling approach for surface water and very shallow groundwater will also take place in phases and will proceed as follows:

- *Conduct initial field sampling and preliminary field screening analysis of surface water throughout AOU-1. This will be accomplished by collecting surface water samples at all locatable seeps, springs, and small surface water bodies suspected of being in contact with groundwater; and collecting sump pump discharge and foundation drain discharge samples at residences. In addition, water samples will be collected from selected Salt Lake City stormwater sewer manholes, located in and downgradient of AOU-1, to determine if groundwater seepage and discharge from foundation drains in AOU-1 is impacting the sewer. Surface samples collected during the investigation will be sent to the EPA CLP lab for analysis of VOCs. It is expected that up to 50 surface water samples will be analyzed for VOCs at the EPA CLP laboratory in accordance with CLP method protocol. Samples from a random subset (20%) of these locations will be analyzed for SVOCs, TAL metals, anions, TDS and pH at the CLP laboratory as appropriate or by the subcontractor laboratory ALS in Salt Lake City. 10% confirmation splits of the surface water samples will be collected and shipped to a different CLP laboratory for the same analysis (VOCs, SVOCs, and TAL metals) for quality assurance. The CLP laboratories will be selected by the EPA Region 8 Sample Coordinator prior to initiation of field activities.*
- *Up to 10 surface water samples will be collected and submitted to the University of Utah Stable Isotope Ratio Facility for Environmental Research for deuterium and oxygen-18 analysis.*
    - *Conduct initial field sampling and preliminary field screening analysis of very shallow groundwater (less than 12 feet below surface). This will be accomplished by manually installing up to 25 shallow temporary groundwater sample points into the water table near ponds, seeps, or springs adjacent to residences or occupied structures. An*

additional 35 temporary shallow groundwater sampling points will be installed to depths up to 30 feet using a truck or tractor-mounted GeoProbe™ Tool (or equivalent). If the GeoProbe™ unit hits refusal before the target depth is reached then permanent monitoring points will be installed as part of the RI for OU-2 at those locations. The mechanically installed sample points will be located along public rights of way throughout and surrounding the portion of the PCE plume in AOU-1 to further determine the extent of groundwater conditions in the areas likely to have the potential for vapor intrusion into occupied buildings. Very shallow groundwater sampling will focus on areas where elevated soil gas and indoor air PCE concentrations are detected at occupied structures, whereas the shallow GeoProbe™ points will focus on identification of the extent of the PCE relative to AOU-1. Up to 10 of the shallow sample points and GeoProbe™ points will be constructed as piezometers and covered with protective surface completions for additional water level measurements and possible additional sampling and analytical testing in the future. The remaining temporary sample points will be abandoned, as soon as sampling and water level measurements are completed. Groundwater samples collected during the investigation will be sent to the EPA CLP laboratory for VOC analysis.

- *Expedited turn-around time will be requested for analysis of preliminary COPCs in groundwater from the CLP laboratory during GeoProbe™ investigation in order to select additional groundwater sampling locations to support either 1) stepping out further from the East Side Springs area if preliminary COPCs are detected or 2) stepping in if no preliminary COPCs are detected. If expedited turn-around is not possible from the CLP laboratory, then samples will be sent to ALS in Salt Lake City for CLP VOC analysis. ALS will provide fast turn data and EPA level 2 type data deliverables to include analytical results and QC sample results. Expedited analysis data used to make real time field decisions will not be validated since the data is being used to screen for preliminary COPC detections and to further delineate sampling locations.*
- *Soil lithology will be performed on all locations in the focus area and 50 percent of locations outside the focus area. Locations to be selected to provide lithologic data throughout the investigation area.*
- *Approximately 50 groundwater samples will be collected and shipped to the CLP lab for VOC analysis in accordance with CLP protocols. Samples from a random subset (10%) of the groundwater sample locations will also be analyzed for SVOCs, total and dissolved metals, and alkalinity, anions, pH, TDS at the CLP laboratory as appropriate or by the subcontractor laboratory ALS in Salt Lake City. The CLP lab will be selected by the EPA Region 8 Sample Coordinator prior to initiation of field activities. It is expected that up to five groundwater samples will be submitted for laboratory analyses of SVOCs and total and dissolved metals.*
- *Temporary monitoring points converted to short term piezometers will be used to measure water levels at least two additional times throughout the year to determine seasonal changes in shallow groundwater elevations. In addition, up to five of the piezometers may be sampled for VOCs, SVOCs, and total and dissolved metals for analysis at a CLP laboratory.*

The field investigation for surface water and very shallow groundwater will commence in the vicinity of the 11 spring and seep locations (pending owner approval for access) previously sampled in 2010 and 2011 (UDEQ/DERR, 2011a, b, c), then proceed to spring and seep locations identified, but not tested during previous investigations (pending access approval), and for groundwater continue at properties whose owners have already requested indoor air pathway evaluation. Although not an explicit objective of the AOU-1 investigation, it is anticipated that surface and groundwater sampling will generally define the southwestern downgradient and western and southern cross-gradient extents of the PCE plume in surface water and in the very shallow groundwater within AOU-1. The resultant groundwater and surface water data will be used to guide additional groundwater characterization and placement of permanent monitoring wells during the subsequent site wide PCE plume RI. Figure 10 provides the approximate initial locations for surface water and shallow groundwater samples.

Table 11 Estimated Numbers of Samples by Media is hereby replaced by the following table:

TABLE 11: Estimated Numbers of Samples by Media
700 South 1600 East PCE Plume, Salt Lake City, Utah

Media	Data Level	Analyses	Estimated Number of Samples	Minimum Number of QC Samples	Rationale	Sample Designation[b]
Surface Water	CLP Protocol	Target List VOCs Field Water Quality Parameters[a]	50	3 field duplicates; 1 trip blank per cooler; 1 rinse blank/field blank per day if necessary	Field screening of identified seeps, springs, other surface water to support vapor intrusion pathway analysis	A-0001-mmddyy-SW-001
Surface Water	CLP Protocol, EPA Lab or Subcontractor Lab	Target List VOCs, SVOCs (including 1,4-dioxane), Metals, Anions, pH Field Water Quality Parameters[a]	10	1 field duplicate; 1 rinse blank/field blank per day if necessary; 1 trip blank per cooler	Predictive pathway analysis and support future groundwater investigation	A-0001-mmddyy-SW-001
Surface Water	CLP Protocol	Target List VOCs, SVOCs (including 1,4-dioxane), and Metals	5	1 trip blank per cooler	Quality assurance split samples	A-0001-mmddyy-SW-001A
Surface Water and Groundwater	SIRFER Standard Operating Procedure	Hydrogen and Oxygen Stable Isotopes	10	NA	Support future groundwater investigation	A-0001-mmddyy-SW-001
Groundwater (first saturated interval)	EPA Method Protocol	PCOPCs Target List (PCE, TCE, DCE, VC) Field Water Quality Parameters[a]	50	1 trip blank per week	Initial groundwater plume delineation samples at proposed locations to support real-time field decisions	A-0001-mmddyy-GW-001
Groundwater (Temporary Sampling Points)	CLP Protocol, EPA Lab or Subcontractor Lab	Target List VOCs, SVOCs (including 1,4-Dioxane), Metals, Anions, Alkalinity, TDS, pH Field Water Quality Parameters[a]	10	1 field duplicate; 1 trip blank per cooler; 1 rinse blank/field blank per day if necessary	Predictive pathway analysis and support future groundwater investigation	A-0001-mmddyy-GW-001

TABLE 11: Estimated Numbers of Samples by Media
700 South 1600 East PCE Plume, Salt Lake City, Utah

Media	Data Level	Analyses	Estimated Number of Samples	Minimum Number of QC Samples	Rationale	Sample Designation[b]
Soil Gas (open areas)	Field Analysis	Direct Read or Tedlar® Bag VOCs - GC/MS	50	5 field duplicates 3 field blanks	Real time soil gas results for field decisions	A-0001-mmddyy-SG-001-ft
Soil Gas (open areas)	Level 4 (CLP Equivalent)	Target List TO-15/TO-15 SIM	15	2 field duplicates	Confirm field results; predictive vapor intrusion pathway analysis	A-0001-mmddyy-SG-001-ft
Soil Gas (near slab)	Field Analysis	Direct Read or Tedlar® Bag VOCs - GC/MS	50	5 field duplicates 3 field blanks	Real time field results to support indoor air pathway evaluation	A-0001-mmddyy-SG-001-ft-
Soil Gas (near slab)	CLP Equivalent (Level 4)/ Definitive	Target List TO-15/TO-15 SIM	15[d]	2 field duplicates	Confirm field results, predictive vapor intrusion pathway analysis	A-0001-mmddyy-SG-001-ft
Indoor Air	Field Analysis	Direct Read Probe VOCs - GC/MS	1100 - 1400	NA	Real Time analyses for indoor air sources, real time determination of indoor air health effects.	A-0001-mmddyy-IA-001-ABC

Media	Data Level	Analyses	Estimated Number of Samples	Minimum Number of QC Samples	Rationale	Sample Designation[(b)]
Soil	CLP Protocol	Target List VOCs, SVOCs, Metals	3	1 field duplicate 1 equip blank Shipped with other samples[(c)]	Data needed to support risk assessment	A-0001-mmddyy-SS-001-ft
Ambient Background Air	Field Analysis	Direct Read Probe VOCs - GC/MS	60	NA	Two samples – one upwind and one downwind of structure tested for indoor air	A-0001-mmddyy-OA-001-OUT
Ambient Background Air	Level 4 (CLP-equivalent)	Target List VOCs - TO-15/TO-15 SIM	6	1 field duplicate Shipped with other samples[(c)]	Confirm field results, determine indoor health effects, evaluate vapor intrusion pathway	A-0001-mmddyy-TO-001-OUT

Notes:

(a) DO, ORP, pH, conductivity, temperature, turbidity.
(b) See QAPP Update Revision 1 (Section 3.3.1) for sample naming convention.
(c) Confirmation sample totals include four locations selected in accordance with QAPP Amendment No. 1 and Minor Modification No. 2.

CLP – Contract Laboratory Program
DCE – cis-1,2-Dichloroethene
GC/MS – Gas chromatograph/mass spectrometer
NA – Not applicable
PCE – Tetrachloroethene
PCOPC – Preliminary contaminant of potential concern
SIM – Selective ion monitoring
SIRFER – Stable Isotopes Ratio Facility for Environmental Research, University of Utah
SVOC – Semivolatile organic compound
TCE – Trichloroethene
TDS – Total dissolved solids
VC – Vinyl chloride
VOC – Volatile organic compound

4. Minor Field Modifcation #5

The Health and Safety Plan (HASP) (Appendix C of the RIWP) has been replaced to reflect the protocols of the new contractor, EA Engineering, Science, and Technology, Inc., PBC (EA). The updated HASP is included with this minor field modification as Attachment 1.

5. Minor Field Modifcation #6

The following information is hereby included in section 6.2.4 of the RIWP for consistency with the QAPP Update Revision 1 with respect to the analysis of surface water samples for deuterium and oxygen-18 analysis (see Minor Field Modification #4):

- Up to 10 surface water samples will be collected for analysis of deuterium and oxygen-18.
- Analysis will be performed at the University of Utah Stable Isotope Ratio Facility for Environmental Research, Salt Lake City, Utah and will follow the SPATIAL/SIRFER CRDS Liquid Water Protocol (Attachment 2).
- The Project Manager for isotope analysis is Suvankhar Chakraborty of the University of Utah Stable Isotope Ratio Facility for Environmental Research.
- The data package deliverable for the stable oxygen and hydrogen isotope analysis will be an EPA Level 2 type package and will include the following information:
  - Cover letter or report title page with laboratory identification, client name and signature of person authorizing report release.
  - Summary of samples received that correlates field sample identification (ID) with the laboratory ID.
  - Chain of custody record.
  - Field ID number.
  - Date received.
  - Date prepared.
  - Date analyzed
  - Preparation and analytical methods.
  - Reference sample results
  - Case narrative that addresses the following information at a minimum:
  - Sample receipt discrepancies
  - Descriptions of all non-conformances in the sample receipt, handling, preparation, analytical and reporting processes, and the corrective action taken in each occurrence.
- The turnaround time for the isotope analysis is anticipated to be 45 days. An expedited turnaround time will likely not be required for the isotope analysis.
- Groundwater is analyzed using an autosampler and Picarro Cavity Ring-Down Spectroscopy (CRDS) system to determine $\delta^{18}O$ and $\delta^{2}H$ ratios.

Quality Control Samples (Lab) for Stable Oxygen and Hydrogen Isotope Parameters in Water
AOU-1 - 700 South 1600 East PCE Plume, Salt Lake City, Utah

QC Sample	Frequency	Method/SOP QC Acceptance Limits - δ^2H	Corrective Action	Person Responsible for Corrective Action	Data Quality Indicator (DQI)	Measurement Performance Criteria
Field Duplicate	1 per sampling event	Standard deviation of calibrated isotopic values for 3 or more replicate injections of the unknown sample must be less than 0.2‰ ($\delta^{18}O$) and 0.75‰ (δ^2H)	Evaluate batch precision for other QC samples and flag data accordingly	Data Reviewer	Precision	RPD less than 50% for detect data
PT[1] Reference Water	Run at beginning of run and after every 8 samples	Not vary by more than 0.9‰ for δ2H and 0.12‰ for δ18O (1 standard deviation)	If monthly values exceed the thresholds, the data from individual runs should be reviewed to identify and remedy potential errors in data processing or any systematic changes in instrument performance and their cause.	Laboratory Supervisor	Precision	Not vary by more than 0.9‰ for δ2H and 0.12‰ for δ18O (1 standard deviation)
PZ[1] Reference Water	1 per sample tray run	Standard deviation should be no more than 20% of the average parameter value across the month	Review data from individual runs to identify and remedy potential error or systematic changes. Reanalyze sample and reassess if necessary	Laboratory Supervisor	Precision	Less than or equal to 20% average over the month
UT[1] Reference Water	1 per sample tray run	Standard deviation should be no more than 20% of the average parameter value across the month	Review data from individual runs to identify and remedy potential error or systematic changes. Reanalyze sample and reassess if necessary	Laboratory Supervisor	Precision	Less than or equal to 20% average over the month

DATE: 2 March 2016

SUBJECT: Minor Field Modifications to the Sampling and Analysis Plan AOU-1: East Side Springs 700 South 1600 East PCE Plume Salt Lake City, Utah (July 2015)

1. Introduction

This document provides a description of minor modifications to the Sampling and Analysis Plan (SAP) AOU-1: East Side Springs 700 South 1600 East PCE Plume Salt Lake City, Utah (October 2014) to provide consistency for sampling methods, analytes, and other details documented in the SAP and the Quality Assurance Project Plan (QAPP). The SAP is included as Appendix A of the Remedial Investigation Work Plan (RIWP) AOU-1: East Side Springs 700 South 1600 East PCE Plume Salt Lake City, Utah (July 2015). Minor Field Modification #1 Protocol for Performing Indoor Air and Near-slab Soil Gas Assessments and Minor Field Modification #2 Clarification of QAPP Amendment Number 1 are included in the Final RIWP as Appendices K and L. Minor Field Modifications #3 - #6 are included in a separate document and detail changes to the RIWP. The following modifications are detailed below:

- Minor Field Modification #7 – Change of analytical method for analysis of 1,4-dioxane (EPA Crosswalk[1] items A6(a)(iv), A6(a)(vii), B1(b), B1(c), B2(a)(i), B2(b), B2(f)(ii), B2(h), B2(i), B3(a)(i), B3(b)(i), B3(d)(i), B4(b)(i), B4(c)(i), B5(a)(i), B6(b), B7(a)(i), B7(b)(i), B8(a)(ii))
- Minor Field Modification #8 – Updates to the analytical methods, parameters, and the sample media on which the analyses will be performed; updates to number of samples, sample locations and depth, analyses, collection methodology, etc. for each of the targeted media; change in use of HAPSITE gas chromatograph/mass spectrometer for field screening of groundwater and surface water samples (EPA Crosswalk[1] items A6(a)(ii), A6(a)(ix), A6(a)(x), A6(a)(xi), A6(a)(xii), B1(f)(i), B1(f)(vi))
- Minor Field Modification #9 – Inclusion of isotope analysis of surface water (EPA Crosswalk[1] items A3, A4(a)(iii), A4(e), A6(a)(x), B4(a)(ii), B4(f))
- Minor Field Modification #10 – Excludes installation of pressure transducers in temporary monitoring points for the 2016 field event (EPA Crosswalk[1] items A6(a)(xiv), B2(a)(ii))
- Minor Field Modification #11 – Clarifies use of the term definitive data (EPA Crosswalk[1] item B1(f)(i), B1(f)(iii), B1(f)(iv), B1(f)(v), B1(f)(vi), B1(f)(viii), B1(f)(ix))
- Minor Field Modification #12 – Updates to sample containers, preservatives, hold times and sample methods (EPA Crosswalk[1] items B2(f)(i), B2(g), B3(a)(ii))

- Minor Field Modification #13 – Removes field screening for SVOCs.

2. Minor Field Modifcation #7

The TO-15 SIM analyte list will include 1, 4-dioxane. Therefore, TO-13 sampling and analysis will not be used for any samples collected during the 2016 sampling event. This field modification is a change to sections 4.1 and 4.2 of the SAP.

3. Minor Field Modifcation #8

The following sections and table from the SAP have been updated for consistency with the QAPP Update Revision 1 with respect to 1) analytical methods, parameters, and the sample media on which the analyses will be performed; 2) number of samples, sample locations and depth, analyses, collection methodology, etc. for each of the targeted media; and 3) change in use of HAPSITE gas chromatograph/mass spectrometer for field screening of groundwater and surface water samples.

Section 4.1 Indoor Air Quality Screening, Characterization, and Verification is hereby replaced with QAPP Update Revision 1 Section 2.3.1 as follows:

The indoor air characterization approach is as follows:

- *Indoor Air Screening step: Access each occupied structure within AOU-1where the occupant/owner has granted access and complete visual inspection for potential indoor VOC sources and conduct resident interview. The indoor air will be analyzed for chlorinated volatile organic compounds (cVOCs) using the field portable GC/MS in quantitation mode. Screening will be conducted on each level (basements and living/working floors. If cVOCs are detected, the portable GC/MS will be run in survey mode to aid identification of background sources of cVOCs such as chemical products and dry-cleaned clothing. If such sources are found, the resident will be asked to relocate the materials from the occupied structure to prepare for real-time air assessment. It is estimated that as many as 300 occupied structures, including residences, schools, daycare facilities, and other businesses, are within the AOU-1 boundaries; however, participation of owners will likely be much less and reduce the actual testing locations, with 30 to 50 structures estimated to be included in the testing.*
- *Indoor Air Characterization step: Conduct real-time assessment of indoor air quality at accessible occupied structures within the AOU-1 area where permission has been obtained. The characterization of indoor air will occur in the breathing zone under both ambient conditions approximately 30 minutes after the indoor source screening step is completed and then after the structure is placed under negative differential pressurization (target differential pressure of 10 pascals, equivalent of 0.04 inches of water, a level that replicates the effects of typical cold season stack effects, between inside and outside) as measured with a portable field manometer. Each structure for which access has been granted within AOU-1will be evaluated for cVOCs, using the portable GC/MS in analyze mode, with testing occurring within the breathing zone on basements and living/working levels of the structure to identify the compounds present in the indoor air. A properly calibrated portable GC/MS in analyze mode is capable of achieving low ppbv to parts per trillion by volume detection limits for PCE and TCE in air. The portable GC/MS will also be used in analyze mode to measure ambient outdoor background concentrations concurrent with the indoor activities. To the extent practical given site access*

considerations and variable wind directions over the period of sampling, one outdoor air sample will be collected associated with each structure.

- *Indoor Air Verification step: Conduct indoor air sampling using Summa canisters equipped with flow regulators to collect 24-hour time-averaged samples in structures where concentrations of the 5 PCOPCs exceed the screening levels shown in RIWP Appendix H. Concurrent measurements for differential air pressure (inside and outside) will be taken during this step to assure samples are representative of conditions that create vapor intrusion. Samples will be sent to a Utah Department of Health (UDOH)-certified laboratory for volatile organic compound (VOC) analysis or VOC-Selective Ion Monitoring (SIM) analysis to achieve lower reporting limits for PCOCs using the EPA Toxic Organics (TO)-15 analytical method. Laboratory testing of indoor air is estimated to occur at approximately 25 structures out of the 30 to 500 expected to be initially assessed in the AOU-1 area, and analysis of up to 40 indoor samples is expected (some structures will require multiple sample locations). Based on Minor Field Modification #1, an additional 4 structures will be sampled to aid the assessment of whether vinyl chloride is present at concentrations below the detection limit using the portable GC/MS. This is needed because the vinyl chloride reporting limit using the portable GC/MS is above the screening level, whereas, the reporting limit for laboratory samples is below the detection limit. The selected structures will be located where groundwater is within 10 to 20 feet of the ground surface and will include:*

  - *One sample outside the Plume where PCE, TCE, and cis-DCE in the indoor air are below the screening levels (SLs) or the detection limit of the HAPSITE® instrument.*
  - *Three samples will be collected inside the area of the Plume where PCE and TCE are equal to or less than their respective SLs but above the instrument detection limits.*

  At least three outdoor (upwind, downwind, and in the center of AOU-1) ambient background samples will be collected during the confirmation sampling activities for laboratory analysis for VOCs using method TO-15.

- *Additional Monitoring Activities: In addition to the initial screening, which will be conducted under cold season and low water table conditions, a second round of assessment and confirmation sampling of indoor air at up to 15 selected outdoor background and indoor air locations, based on the potential for indoor air exposure, will be conducted during Spring 2016. This phase will be conducted in the vicinity of known PCE contamination based on results from the initial sampling. The area of AOU-1 where PCE was previously detected above the screening level in indoor air samples and shallow groundwater is anticipated is known as the focus area. The re-testing will be conducted using both real-time field analyses (portable GC/MS) and confirmatory laboratory analysis using Summa canisters for sample collection and offsite laboratory analysis.*

Section 4.2 Near-slab Soil Gas Investigation is hereby replaced with QAPP Update Revision 1 Section

2.3.2 as follows:

The near-slab soil gas characterization approach will be implemented concurrent with the indoor air characterization to identify and characterize cVOCs present in soils adjacent to tested structures, as follows:

> *Near-slab Soil Gas Characterization step: Conduct soil gas characterization adjacent to structures screened and assessed for vapor intrusion where the property owner agreed to soil gas sampling and sampling is practical given site conditions. Soil vapor probes will be driven adjacent to the structure foundation to a depth approximately 6 inches below the base of the foundation or to the top of the water table, whichever occurs first. Samples will be collected with a vacuum pump and Tedlar® bags, field screened with a photoionization detector (PID) and multigas meter, then a second sample collected in the same manner and field-screened with the portable GC/MS in analyze mode to identify and quantify any cVOCs present in soil pore space adjacent to structures. At locations where groundwater is not encountered at the base of the foundation, the probe rod will be driven another 5 feet after the initial sample is collected, if soil conditions allow, to obtain another sample for vertical delineation data for soil gas. If groundwater is encountered, the approximate depth to water will be measured and recorded. It is anticipated that up to 50 locations will be field screened for near-slab soil gas concentrations during the study.*

- *Near-slab Soil Gas Characterization Verification step: Collect soil gas samples in a Summa canister and submit selected soil gas samples for full volatile organics (TO-15) analysis at a UDOH certified laboratory at any location where a near-slab characterization sample exceeds the 11.0 µg/m^3 (1.62 ppbv) SL for PCE or where soil gas vapors are found to be elevated 10 times the RSL for the detected VOC. In addition, selected locations where the field portable GC/MS did not detect VOCs in soil gas will be sampled to confirm results. Sampling for laboratory analyses will be accomplished using Summa canisters equipped with flow regulators to collect 24-hour time-averaged samples from the soil vapor probes. Based on the expected number of buildings located within the area where soil gas impact caused by the PCE plume is most likely to occur, laboratory testing of soil gas is estimated to occur at up to 15 locations.*

- *Conduct additional near-slab, soil floor and crawl space for TO-15 analysis, using a UDOH certified and EPA-approved laboratory, at structure locations identified during the indoor air field characterization and during the field investigation as having high potential for vapor intrusion into indoor air. These locations are proposed to provide additional high-quality lab data for human health risk assessment resulting from the vapor intrusion pathway.*

Near-slab testing was chosen in lieu of sub-slab testing due to the presence of extremely shallow groundwater that occurs at or very near the slabs of many residences as indicated by numerous sump pumps and discharging footer drains. The likelihood of causing groundwater to leak into the basement of a structure by penetrating the slab to install testing apparatus was deemed too risky by the project team.

The indoor air assessment/characterization and near-slab soil gas sampling will commence at the same residences or occupied structures where owners have already indicated they will allow indoor air testing, and then pending permission to access additional properties, proceed to structure locations adjacent to the previously identified springs and seeps. It is anticipated that additional property owners may need to be actively recruited by VA in some portions of AOU-1 to fill data gaps, but at least 36 owners have already indicated a willingness to allow testing. The initial locations for indoor air and soil gas sampling are shown on Figure 4.

Section 4.3 Open-field Soil Gas Investigation is hereby replaced with QAPP Update Revision 1 Section

2.3.3 as follows:

Open-field soil gas data will be collected to provide a means of estimating the plume impacted area and to aid in evaluation of vapor intrusion potential. Concurrent with or immediately following the initial indoor air quality characterization steps and near-slab soil gas characterization, the investigative sampling approach for open field soil gas will proceed as follows:

- *Conduct field screening of soil gas levels and vertically profile the soil gas concentrations of PCE and daughter products in the vadose zone by manually or mechanically installing unsaturated (vadose) zone soil vapor sampling points near historically cVOC-impacted seeps and springs and in selected locations adjacent to streets/sidewalks (open field samples) in AOU-1. The field screening will be conducted by collecting soil gas samples in Tedlar bags for subsequent analysis using the field portable GC/MS equipment or the GC/MS probe will be connected directly to the sampling point. It is anticipated that soil gas samples will be collected from locations adjacent to the six spring identified during the previous investigations that contained PCE; then at the six spring locations that did not contain PCE; and then expand the sampling program to additional spring locations within AOU-1 as they are identified during field activities, up to an expected total of 50 samples.*
- *Conduct additional open field soil gas sampling for TO-15 analysis, using a UDOH certified and EPA-approved laboratory.*

The open field soil gas sampling (near seeps or springs and along public right of ways) will commence at residences or occupied structures where owners have already indicated they will allow access for indoor air testing, and then pending permission to access, proceed to structure locations adjacent to the previously identified springs or seeps, and at selected locations on public rights of way.

Section 4.4 Surface Water and Shallow Groundwater Investigation is hereby replaced with QAPP Update Revision 1 Section 2.3.4 as follows:

Concurrent with or immediately following the initial indoor air quality characterization steps, the general investigative sampling approach for surface water and very shallow groundwater will also take place in phases and will proceed as follows:

- *Conduct initial field sampling and preliminary field screening analysis of surface water throughout AOU-1. This will be accomplished by collecting surface water samples at all locatable seeps, springs, and small surface water bodies suspected of being in contact with groundwater; and collecting sump pump discharge and foundation drain discharge samples at residences. In addition, water samples will be collected from selected Salt Lake City stormwater sewer manholes, located in and downgradient of AOU-1, to determine if groundwater seepage and discharge from foundation drains in AOU-1 is impacting the sewer. Surface samples collected during the investigation will be sent to the EPA CLP lab for analysis of VOCs. It is expected that up to 50 surface water samples will be analyzed for VOCs at the EPA CLP laboratory in accordance with CLP method protocol. Samples from a random subset (20%) of these locations will be analyzed for SVOCs, TAL metals, anions, TDS and pH at the CLP laboratory as appropriate or by the subcontractor laboratory ALS in Salt Lake City. 10% confirmation splits of the surface water samples will be collected and shipped to a different CLP laboratory for the same analysis (VOCs, SVOCs, and TAL metals) for quality assurance. The*

CLP laboratories will be selected by the EPA Region 8 Sample Coordinator prior to initiation of field activities.

- *Up to 10 surface water samples will be collected and submitted to the University of Utah Stable Isotope Ratio Facility for Environmental Research for deuterium and oxygen-18 analysis.*

    - *Conduct initial field sampling and preliminary field screening analysis of very shallow groundwater (less than 12 feet below surface). This will be accomplished by manually installing up to 25 shallow temporary groundwater sample points into the water table near ponds, seeps, or springs adjacent to residences or occupied structures. An additional 35 temporary shallow groundwater sampling points will be installed to depths up to 30 feet using a truck or tractor-mounted GeoProbe™ Tool (or equivalent). If the GeoProbe™ unit hits refusal before the target depth is reached then permanent monitoring points will be installed as part of the RI for OU-2 at those locations. The mechanically installed sample points will be located along public rights of way throughout and surrounding the portion of the PCE plume in AOU-1 to further determine the extent of groundwater conditions in the areas likely to have the potential for vapor intrusion into occupied buildings. Very shallow groundwater sampling will focus on areas where elevated soil gas and indoor air PCE concentrations are detected at occupied structures, whereas the shallow GeoProbe™ points will focus on identification of the extent of the PCE relative to AOU-1. Up to 10 of the shallow sample points and GeoProbe™ points will be constructed as piezometers and covered with protective surface completions for additional water level measurements and possible additional sampling and analytical testing in the future. The remaining temporary sample points will be abandoned, as soon as sampling and water level measurements are completed. Groundwater samples collected during the investigation will be sent to the EPA CLP laboratory for VOC analysis.*

- *Expedited turn-around time will be requested for analysis of preliminary COPCs in groundwater from the CLP laboratory during GeoProbe™ investigation in order to select additional groundwater sampling locations to support either 1) stepping out further from the East Side Springs area if preliminary COPCs are detected or 2) stepping in if no preliminary COPCs are detected. If expedited turn-around is not possible from the CLP laboratory, then samples will be sent to ALS in Salt Lake City for CLP VOC analysis. ALS will provide fast turn data and EPA level 2 type data deliverables to include analytical results and QC sample results. Expedited analysis data used to make real time field decisions will not be validated since the data is being used to screen for preliminary COPC detections and to further delineate sampling locations.*

- *Soil lithology will be performed on all locations in the focus area and 50 percent of locations outside the focus area. Locations to be selected to provide lithologic data throughout the investigation area.*

- *Approximately 50 groundwater samples will be collected and shipped to the CLP lab for VOC analysis in accordance with CLP protocols. Samples from a random subset (10%) of the groundwater sample locations will also be analyzed for SVOCs, total and dissolved metals, and alkalinity, anions, pH, TDS at the CLP laboratory as appropriate or by the subcontractor laboratory ALS in Salt Lake City. The CLP lab will be selected by the EPA Region 8 Sample*

Coordinator prior to initiation of field activities. It is expected that up to five groundwater samples will be submitted for laboratory analyses of SVOCs and total and dissolved metals.

- *Temporary monitoring points converted to short term piezometers will be used to measure water levels at least two additional times throughout the year to determine seasonal changes in shallow groundwater elevations. In addition, up to five of the piezometers may be sampled for VOCs, SVOCs, and total and dissolved metals for analysis at a CLP laboratory.*

The field investigation for surface water and very shallow groundwater will commence in the vicinity of the 11 spring and seep locations (pending owner approval for access) previously sampled in 2010 and 2011 (UDEQ/DERR, 2011a, b, c), then proceed to spring and seep locations identified, but not tested during previous investigations (pending access approval), and for groundwater continue at properties whose owners have already requested indoor air pathway evaluation. Although not an explicit objective of the AOU-1 investigation, it is anticipated that surface and groundwater sampling will generally define the southwestern downgradient and western and southern cross-gradient extents of the PCE plume in surface water and in the very shallow groundwater within AOU-1. The resultant groundwater and surface water data will be used to guide additional groundwater characterization and placement of permanent monitoring wells during the subsequent site wide PCE plume RI. Figure 10 provides the approximate initial locations for surface water and shallow groundwater samples.

Table 1 Estimated Numbers of Samples by Media is hereby replaced by the following table:

TABLE 1: Estimated Numbers of Samples by Media
700 South 1600 East PCE Plume, Salt Lake City, Utah

Media	Data Level	Analyses	Estimated Number of Samples	Minimum Number of QC Samples	Rationale	Sample Designation[b]
Surface Water	CLP Protocol	Target List VOCs Field Water Quality Parameters[a]	50	3 field duplicates; 1 trip blank per cooler; 1 rinse blank/field blank per day if necessary	Field screening of identified seeps, springs, other surface water to support vapor intrusion pathway analysis	A-0001-mmddyy-SW-001
Surface Water	CLP Protocol, EPA Lab or Subcontractor Lab	Target List VOCs, SVOCs (including 1,4-dioxane), Metals, Anions, pH Field Water Quality Parameters[a]	10	1 field duplicate; 1 rinse blank/field blank per day if necessary; 1 trip blank per cooler	Predictive pathway analysis and support future groundwater investigation	A-0001-mmddyy-SW-001
Surface Water	CLP Protocol	Target List VOCs, SVOCs (including 1,4-dioxane), and Metals	5	1 trip blank per cooler	Quality assurance split samples	A-0001-mmddyy-SW-001A
Surface Water and Groundwater	SIRFER Standard Operating Procedure	Hydrogen and Oxygen Stable Isotopes	10	NA	Support future groundwater investigation	A-0001-mmddyy-SW-001
Groundwater (first saturated interval)	EPA Method Protocol	PCOPCs Target List (PCE, TCE, DCE, VC) Field Water Quality Parameters[a]	50	1 trip blank per week	Initial groundwater plume delineation samples at proposed locations to support real-time field decisions	A-0001-mmddyy-GW-001
Groundwater (Temporary Sampling Points)	CLP Protocol, EPA Lab or Subcontractor Lab	Target List VOCs, SVOCs (including 1,4-Dioxane), Metals, Anions, Alkalinity, TDS, pH Field Water Quality Parameters[a]	10	1 field duplicate; 1 trip blank per cooler; 1 rinse blank/field blank per day if necessary	Predictive pathway analysis and support future groundwater investigation	A-0001-mmddyy-GW-001

TABLE 1: Estimated Numbers of Samples by Media
700 South 1600 East PCE Plume, Salt Lake City, Utah

Media	Data Level	Analyses	Estimated Number of Samples	Minimum Number of QC Samples	Rationale	Sample Designation[b]
Soil Gas (open areas)	Field Analysis	Direct Read or Tedlar® Bag VOCs - GC/MS	50	5 field duplicates 3 field blanks	Real time soil gas results for field decisions	A-0001-mmddyy-SG-001-ft
Soil Gas (open areas)	Level 4 (CLP Equivalent)	Target List TO-15/TO-15 SIM	15	2 field duplicates	Confirm field results; predictive vapor intrusion pathway analysis	A-0001-mmddyy-SG-001-ft
Soil Gas (near slab)	Field Analysis	Direct Read or Tedlar® Bag VOCs - GC/MS	50	5 field duplicates 3 field blanks	Real time field results to support indoor air pathway evaluation	A-0001-mmddyy-SG-001-ft-
Soil Gas (near slab)	CLP Equivalent (Level 4)/ Definitive	Target List TO-15/TO-15 SIM	15[d]	2 field duplicates	Confirm field results, predictive vapor intrusion pathway analysis	A-0001-mmddyy-SG-001-ft
Indoor Air	Field Analysis	Direct Read Probe VOCs - GC/MS	1100 - 1400	NA	Real Time analyses for indoor air sources, real time determination of indoor air health effects.	A-0001-mmddyy-IA-001-ABC
Indoor Air	Level 4 (CLP Equivalent)	Target List VOCs TO-15/ TO-15 SIM	55[d]	6 field duplicates[c]	Confirm field results, determine indoor health effects, evaluate vapor intrusion pathway	A-0001-mmddyy-TO-001-ABC

TABLE 1: Estimated Numbers of Samples by Media
700 South 1600 East PCE Plume, Salt Lake City, Utah

Media	Data Level	Analyses	Estimated Number of Samples	Minimum Number of QC Samples	Rationale	Sample Designation[b]
Soil	CLP Protocol	Target List VOCs, SVOCs, Metals	3	1 field duplicate 1 equip blank Shipped with other samples[c]	Data needed to support risk assessment	A-0001-mmddyy-SS-001-ft
Ambient Background Air	Field Analysis	Direct Read Probe VOCs - GC/MS	60	NA	Two samples – one upwind and one downwind of structure tested for indoor air	A-0001-mmddyy-OA-001-OUT
Ambient Background Air	Level 4 (CLP-equivalent)	Target List VOCs - TO-15/TO-15 SIM	6	1 field duplicate Shipped with other samples[c]	Confirm field results, determine indoor health effects, evaluate vapor intrusion pathway	A-0001-mmddyy-TO-001-OUT

Notes:

(a) DO, ORP, pH, conductivity, temperature, turbidity.
(b) See QAPP Update Revision 1 (Section 3.3.1) for sample naming convention.
(c) Confirmation sample totals include four locations selected in accordance with QAPP Amendment No. 1 and Minor Modification No. 2.

CLP – Contract Laboratory Program
DCE – cis-1,2-Dichloroethene
GC/MS – Gas chromatograph/mass spectrometer
NA – Not applicable
PCE – Tetrachloroethene
PCOPC – Preliminary contaminant of potential concern
SIM – Selective ion monitoring
SIRFER – Stable Isotopes Ratio Facility for Environmental Research, University of Utah
SVOC – Semivolatile organic compound
TCE – Trichloroethene
TDS – Total dissolved solids
VC – Vinyl chloride
VOC – Volatile organic compound

4. Minor Field Modifcation #9

The following information is hereby included in the SAP for consistency with the QAPP Update Revision 1 with respect to the analysis of surface water samples for deuterium and oxygen-18 analysis (see Minor Field Modification #8):

- Up to 10 surface water samples will be collected for analysis of deuterium and oxygen-18.
- Analysis will be performed at the University of Utah Stable Isotope Ratio Facility for Environmental Research, Salt Lake City, Utah and will follow the SPATIAL/SIRFER CRDS Liquid Water Protocol (Attachment 1).
- The Project Manager for isotope analysis is Suvankhar Chakraborty of the University of Utah Stable Isotope Ratio Facility for Environmental Research. Mr. Chakraborty is hereby included in the SAP distribution list.
- The data package deliverable for the stable oxygen and hydrogen isotope analysis will be an EPA Level 2 type package and will include the following information:
  - Cover letter or report title page with laboratory identification, client name and signature of person authorizing report release.
  - Summary of samples received that correlates field sample identification (ID) with the laboratory ID.
  - Chain of custody record.
  - Field ID number.
  - Date received.
  - Date prepared.
  - Date analyzed
  - Preparation and analytical methods.
  - Reference sample results
  - Case narrative that addresses the following information at a minimum:
  - Sample receipt discrepancies
  - Descriptions of all non-conformances in the sample receipt, handling, preparation, analytical and reporting processes, and the corrective action taken in each occurrence.
- The turnaround time for the isotope analysis is anticipated to be 45 days. An expedited turnaround time will likely not be required for the isotope analysis.
- Groundwater is analyzed using an autosampler and Picarro Cavity Ring-Down Spectroscopy (CRDS) system to determine $\delta^{18}O$ and $\delta^{2}H$ ratios.

5. Minor Field Modifcation #10

Pressure transducers will not be installed in temporary monitoring wells per the QAPP Update Revision 1. This will affect Section 5.1.5 and 5.9 of the SAP.

6. Minor Field Modifcation #11

Updates to the SAP for the clarification of the term definitive data are documented in the errata sheet (General Erratum #3) which states that the terms “screening” and “definitive” are hereby removed throughout the document to be consistent with the use of these terms in the QAPP Update Revision 1.

7. Minor Field Modification #12

Table 4 Sample Collection Summary: Aqueous/Liquid (CLP Methods) and Table 5 Sample Collection Summary: Vapor/Gases are hereby replaced by QAPP Update Revision 1 Table 16 (Attachment 2).

8. Minor Field Modifcation #13

Analysis of field samples will be performed for VOCs but not for SVOCs for the 2016 field event. The PCOPC 1,4-dioxane will be analyzed using the VOC TO-15 SIM method. This change has been addressed by Minor Field Modification #7.

CRDS Water Isotope Analyzer Operation

Created 2014 by Crystal Tulley-Cordova

Revised 3/10/2015 by Kali Blevins

Part 1 – Sample Preparation

1. Fill standard and sample vials
    a. Pipette samples
        i. Pipette 0.5 mL from sample container into 2mL crimp-top vial. Use a separate, clean pipette tip for each sample. Discard used tips into a beaker for washing and re-use.
        ii. Use crimper to seal lid. Check to make sure the lid is tight (i.e. does not rotate on the top of the vial) and cleanly crimped. If the crimper is not creating a tight seal, you can adjust it with an Allen wrench.
        iii. Pipette samples 8 at a time, writing each sample name or a unique abbreviation of each sample name on each 2 mL vial with a sharpie.
        iv. Place samples in the sample tray leaving the first four plate locations empty and leaving one plate location blank between each group of eight samples. Empty locations will be used for reference waters. A maximum of 56 samples should be run at a time.
    b. Pipette reference water
        i. In order to limit evaporation, minimize the amount of time the reference waters are out of the refrigerator and the amount of time the cap is off of the reference water bottles. After pipetting reference waters, immediately replace the cap securely on the bottle and parafilm tightly around the cap.
        ii. Pipette 0.5 mL from container into 2mL crimp-top vial. Use a separate, clean pipette tip for each reference water. Discard used tips into a beaker for washing and re-use.
        iii. Use crimper to seal lid. Check to make sure the lid is tight (i.e. does not rotate on the top of the vial) and cleanly crimped.
        iv. Fill 1 vial with reference water PZ and 1 with reference water UT. These primary references are used to calibrate each run.
        v. Fill 1 vial with PT to put at the beginning of the run, 1 additional vial to run before every 8 samples, and 1 to be run in the last plate location. This secondary reference water is used to quality check the accuracy of the calibration regression and to generate a drift correction in each run. An example plate map is shown below.

Table 1. Example plate map with maximum plate locations filled

64	Sample54	65	Sample55	66	Sample56	67	PT	68		69		70

Part 2 – Instrument Preparation

2. Clean syringe
    a. Unplug Autosampler and carefully remove syringe
    b. Don gloves (latex or nitrile), a lab coat, and safety goggles
    c. Open chemical fume hood sash, turn on light, and ensure that it is functioning properly with adequate air flow
    d. Lay down 2 Kimwipes; one to lay syringe on and another for ejecting solvent onto
    e. Use solvent (1-methyl-2-pyrrolidinone) from cabinet below hood to clean the syringe
        i. Insert syringe through the septum on solvent bottle, preferably targeting a previously punctured location. Be careful not to bend the syringe tip.
        ii. Extract solvent with syringe to capacity by moving plunger slowly until it comes out of the syringe. Rotate the plunger as you remove it to thoroughly clean the syringe. Rotating may also help to free the plunger if it becomes stuck.
        iii. Remove syringe from solvent bottle and eject solvent from syringe onto Kimwipe by replacing the plunger in the syringe and fully depressing it.
        iv. Repeat process at least three times or as many times as necessary until the plunger moves smoothly and easily in the syringe. If you cannot get the plunger to move freely it might need to be replaced. Note that broken syringes must be discarded in the sharps container.
        v. Once complete, re-cap the solvent bottle and return to storage under hood. Leave the Kimwipe with the ejected solvent in the fume hood until the solvent has completely evaporated before discarding.
    f. Use deionized water to rinse the syringe three times, fully filling and emptying the syringe each time
    g. Dry syringe
        i. Remove the plunger from the syringe, wiping it with a Kimwipe
        ii. Insert tip of syringe into the piece of blue tubing near the compressed air station, preferably locating a pre-existing hole and being careful not to bend the syringe
        iii. Place the opening of the tubing loosely against the air nozzle (do not try to force tubing over the nozzle)
        iv. Turn the air on and let it run until any water has been blown out of the syringe

v. Check the syringe to ensure that no water droplets remain and then replace the plunger. This eliminates the possibility of air bubbles that might affect the fill volume of the syringe.

h. Replace Syringe
   i. Plug the power supply to the autosampler back in
   ii. On the CRDS computer desktop, open the Autosampler Controller and press Chg Syringe button and wait for the syringe holder to move into position
   iii. Place syringe in syringe holder, making sure body and plunger are in holding locations
   iv. Press Swap Done button on Autosampler Controller

3. Fill out instrument log
   a. Open the sample log file on the desktop of the CRDS instrument computer
   b. Input the following information: date, time, initials, project name, number of samples, number of injections, N_2 pressure from the primary regulator on the N_2 tank
      i. N_2 pressure on the primary regulator should be > 150 psi. If the value is lower do not start the run. Wait for all instruments to finish their runs and then replace the tank will a full one. If no full spare tanks remain on the rack alert the SPATIAL facility manager who will order replacements.
      ii. N_2 pressure on the red, secondary regulator (on the bench top near the tanks) should be 2 (+/- 0.3) psi. If outside this range alert the SPATIAL facility manger. This value does not need to be recorded in the log.
   c. Look at the previous row to determine whether the septum should be changed – the septum should be changed every 300 injections. See section 5 for instructions on changing the septum. Indicate with an "X" if you have changed the septum or syringe.
4. Fill out sample ID file
   a. Open "Sample_list_template.csv" from desktop
   b. In the runfiles folder, save as "YYMMDD_project_HIDS20XX"
   c. Fill out template with sample IDs and project identifiers
5. Change septum
   a. The septum needs to be changed every 300 injections. Check run log to see if it needs to be replaced.
   b. Unscrew the injection port of the vaporizer, using fingers or tool that sits on top of the injection port to grasp and turn the ceramic top of the port. Caution: ceramic surface is warm, but metal parts at base of injection port will be hot.
   c. Remove old septum, replace with new septum. Check to see that new septum is centered.
   d. Replace injection port and hand-tighten
6. Check glass wool
   a. Make sure the glass wool container remains dry and no condensation is apparent in the vial. Check to make sure that the aquarium pump is working correctly and air is being forced through the opening at the top of the vial.

7. Check that background H_2O concentration reported in the data viewer window is below 100 ppm. If not, check that the N_2 tank regulator valve is open and the primary and secondary regulator pressures are correct (see #3).
8. Open Coordinator Launcher
    a. Don't press launch yet
    b. Make sure High Precision program ("AI High Precision" on some instruments) is selected
9. Open Autosampler Control
    a. Check that the following settings are correct:
        i. Row 1 is set for samples 1-4 and ten injections
        ii. Row 2 is set for samples 5-67 and four injections
        iii. If running less than 67 vials, update number in row 2 to match the position of the final sample in the autosampler tray
        iv. Method should be set as 'GJB rinse' (see Appendix)
    b. Click the Run button
10. After clicking Run in Autosampler Control, click the Launch button in Coordinator Launcher
11. Watch first few samples before leaving lab to ensure no problems at start of analysis
12. **Do not open OpenOffice files while run in progress, otherwise raw data will be lost and not saved to .csv file**

Part 3 – Data Processing

13. Run ChemCorrect
    a. After analysis has completed, close the Coordinator Launcher and Autosampler Control and open ChemCorrect from the desktop of the Picarro computer
    b. Click the Source button and navigate to the file with the correct date
    c. Click the 'OK' button to run ChemCorrect
    d. Examine the results to ensure that no samples show evidence for contamination, as indicated by red highlighting in the results window. Any samples flagged for contamination should be treated with activated charcoal and re-run.
        i. Uncap sample vial, add 0.5 mg activated charcoal, recap, and invert 3 times.
        ii. Allow treated sample to rest for 12 or more hours before re-analyzing.
        iii. If the same sample is flagged for contamination by ChemCorrect a second time, the sample should be transferred to the SIRFER lab for analysis by IRMS.
14. Process data
    a. Ensure that the data has been synced to the Dropbox folder and can be accessed from a computer with R installed on it.
    b. Open R and open the R script 'CRDS_liquid_3.R'
    c. Following the instructions in the R script, process the data and write an excel workbook with the data and quality assurance information. Also see the information in CRDS Data Processing R Scripts protocol.
    d. Examine the quality control and final sample data by running the appropriate functions in R and/or examining the information written to the excel workbook.

i. Quality control metrics for the run are compared against the criteria stored in the file "CRDS_liquid_parameters.csv". If any of the quality metrics have been violated, as indicated by the 'Ignore_Run' flag, troubleshooting will be necessary to determine why and all of the samples should be rerun. Examine the memory correction terms, the raw and memory-corrected values for the primary reference waters, the raw, memory-corrected, and drift-corrected values for the secondary reference water to determine what may have caused the quality parameter to be violated and correct for this before running samples again.

ii. Raw data for any individual samples that have violated the quality parameters, as indicated by an 'Ignore' flag, but was not flagged by ChemCorrect, should be reviewed manually.

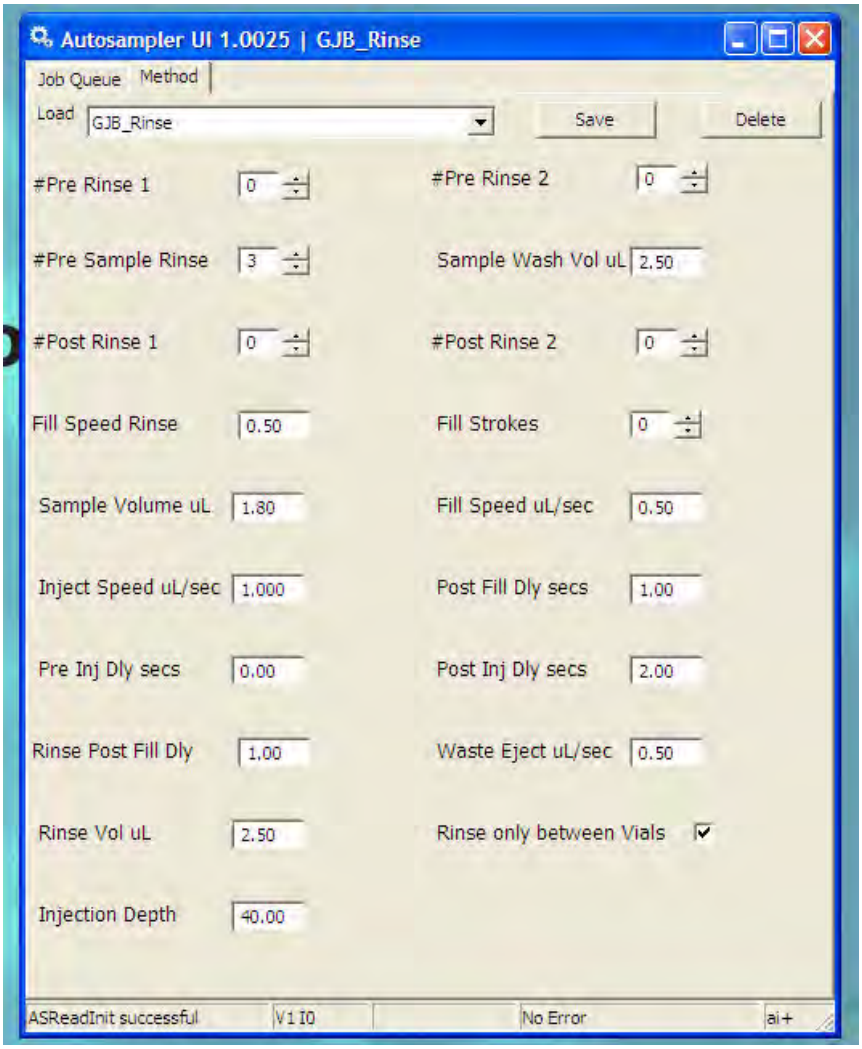
1. Open the .csv instrument output file for the run and identify the analysis results for the four injections of the problem sample.
2. If one of the four injections is a clear outlier (> 3 standard deviations different from the other 3 in terms of H_2O concentration or either isotope ratio) the results for this injection can be deleted from the file. Highlight column "F" and all columns to the right for the row representing the outlier injection and delete the contents. Save the results file as a copy, appending "toAnalyze" at the end of the file name. No more than injection can be deleted for any given sample. Re-process the data file using the R scripts before exporting the results to the database and excel file.
3. If there is no clear outlier or if more than one injection appears to be an outlier the sample should be re-analyzed. If the sample has already been re-run twice, it should be transferred to SIRFER to be analyzed by IRMS.

e. After examining the data, run the appropriate functions in R to upload the data to the database and export an Excel results file.

Part 4 – Sample Disposal

15. Keep 2 mL sample vials in fridge for two weeks after returning data in case some need to be re-run. After this window, discard used sample vials in Broken Glass box.

Appendix – GJB_rinse autosampler method



Attachment 2

THIS PAGE INTENTIONALLY LEFT BLANK

containers in which they were received from the laboratory. The chain-or-custody record will be placed in one of the boxes.

Commercial carriers are not required to sign the chain-of-custody record if it is sealed inside the shipping cooler and the custody seals remain intact. The laboratories are responsible for storing the samples in a secure location and following chain-of-custody procedures.

Soil and water samples will be collected in certified clean containers provided by the project laboratory. Air samples for TO-15 and TO-15 SIM analysis will be collected in individually clean certified Summa canisters with certified clean flow controllers. The requirements for sample volumes, sampling containers, preservation, and holding times are summarized in Table 16 below.

Samplers are responsible for shipping samples to the appropriate non-CLP and CLP-assigned laboratory for analysis. Samplers may contact their RSCC to obtain their laboratory assignment notification.

TABLE 16: Recommended Sample Container, Preservation, and Holding Time

AOU-1 - 700 South 1600 East PCE Plume, Salt Lake City, Utah

Parameter	Method	Matrix	Holding Time (From Date Sampled)	Container	Preservative
Organics					
VOCs	SOM02.2	Soil	48 hours to preservation, Encore samplers 14 days from sample collection	4 x 5g Encore[2]	4ºC (± 2ºC)
				1 x 4 oz glass jar for moisture content	
VOCs	SOM02.2	Water	14 days	3 x 40 ml glass VOA Vial[1,2]	4ºC (± 2ºC), HCl to pH < 2
SVOCs	SOM02.2	Soil	14 days to extraction, 40 days to analysis	150 grams minimum in one 8-ounce wide mouth glass jar[2]	4ºC (± 2ºC)
SVOCs	SOM02.2	Water	7 days to extraction, 40 days to analysis	1 x one liter wide mouth glass bottle	4ºC (± 2ºC)
VOCs	TO-15/ TO-15 SIM	Air	30 days	1L or 6L Summa Canister	NA
SVOCs	TO-13	Air	30 days	Polyurethane Foam (PUF cartridge or XAD-2 resin cartridge	N/A
Inorganic					
Metals (except Mercury)	ISM02.2	Water	180 days	1L polyethylene bottle [2]	4ºC (± 2ºC)), HNO_3 to pH < 2
Metals (except Mercury)	ISM02.2	Soil	180 days	Fill one 8-ounce wide mouth glass jar	4ºC (± 2ºC)
Mercury	ISM02.2	Water	28 days	1L polyethylene bottle [2]	4ºC (± 2ºC)), HNO_3 to pH < 2
Mercury	ISM02.2	Soil	28 days	Fill one 8-ounce wide mouth glass jar	4ºC (± 2ºC)

TABLE 16: Recommended Sample Container, Preservation, and Holding Time

AOU-1 - 700 South 1600 East PCE Plume, Salt Lake City, Utah

Parameter	Method	Matrix	Holding Time (From Date Sampled)	Container	Preservative
General Chemistry					
Chloride, Nitrate Sulfate	E300.0	Water	28 days, Nitrate 48 hours	1L polyethylene bottle	4ºC (± 2ºC)
pH	E 150.1	Water	Upon receipt at lab or within 24 hours	250 ml polyethylene bottle	4ºC (± 2ºC)
TDS	SM2540C	Water	7 days	1L polyethylene bottle	4ºC (± 2ºC)
Alkalinity	SM2320B	Water	14 days	1L polyethylene bottle	4ºC (± 2ºC)
Stable Oxygen and Hydrogen Isotopes	CRDS	Water	180 days	2 x 20 ml glass vial	4ºC (± 2ºC)

3.3.3 *Chain-of-Custody*

A chain-of-custody record (Attachment 5) establishes the documentation necessary to trace sample possession from time of collection through sample analysis and final disposition and serves to document the specific analyses requested from the laboratory. A sample is in the custody of a person if any of the following criteria are met:

- the sample is in a person's physical possession;
- the sample is in a person's view after being in his or her physical possession;
- the sample was in a person's physical possession and was then locked up or sealed to prevent tampering; and/or
- the sample is kept in a secured area.

The chain-of-custody in Attachment 5 is included as an example form. For samples being submitted to the CLP laboratory, a custody tracking software called Scribe will be used. An electronic chain-of-custody record created using the Scribe software contains basic header
